NOTICE TO
FLOOD INSURANCE STUDY USERS

Communities participating in the National Flood Insurance Program have established repositories of flood hazard data for floodplain management and flood insurance purposes. This Flood Insurance Study (FIS) may not contain all data available within the repository. It is advisable to contact the community repository for any additional data.

Part or all of this FIS may be revised and republished at any time. In addition, part of this Preliminary FIS may be revised by the Letter of Map Revision process, which does not involve republication or redistribution of the FIS. It is, therefore, the responsibility of the user to consult with community officials and to check the community repository to obtain the most current FIS components.

Initial Countywide FIS Effective Date: May 17, 2005

Revised Countywide FIS Effective Date: January 29, 2021

**FLOOD INSURANCE STUDY
ROCKINGHAM COUNTY, NEW HAMPSHIRE
(ALL JURISDICTIONS)**

1.0 INTRODUCTION

1.1 Purpose of Study

This countywide Flood Insurance Study (FIS) investigates the existence and severity of flood hazards in, or revises and updates previous FISs/Flood Insurance Rate Maps (FIRMs) for, the geographic area of Rockingham County, including: the City of Portsmouth; the Towns of Atkinson, Auburn, Brentwood, Candia, Chester, Danville, Deerfield, Derry, East Kingston, Epping, Exeter, Fremont, Greenland, Hampstead, Hampton, Hampton Falls, Kensington, Kingston, Londonderry, New Castle, Newfields, Newington, Newmarket, Newton, North Hampton, Northwood, Nottingham, Plaistow, Raymond, Rye, Sandown, Salem, Seabrook, South Hampton, Stratham, and Windham; and the Seabrook Beach Village District (hereinafter referred to collectively as Rockingham County).

This FIS aids in the administration of the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973. This study has developed flood risk data for various areas of the county that will be used to establish actuarial flood insurance rates. This information will also be used by the communities of Rockingham County to update existing floodplain regulations as part of the Regular Phase of the National Flood Insurance Program (NFIP), and by local and regional planners to further promote sound land use and floodplain development. Minimum floodplain management requirements for participation in the NFIP are set forth in the Code of Federal Regulations at 44 CFR, 60.3.

In some States or communities, floodplain management criteria or regulations may exist that are more restrictive or comprehensive than the minimum Federal requirements. In such cases, the more restrictive criteria take precedence and the State (or other jurisdictional agency) will be able to explain them.

This FIS report presents the contents of original community-based FIS reports as well as two updates. The first update was completed in 2005, when the community reports were combined into a countywide report and the Flood Insurance Rate Maps were presented in digital format. The second update was completed in 2013, when new coastal and riverine analyses were performed in 14 coastal communities in the eastern portion of Rockingham County.

Additional information regarding the 2013 update is included under the heading “The January 29, 2021 Countywide Revision” located within appropriate sections throughout this report.

1.2 Authority and Acknowledgments

The sources of authority for this FIS are the National Flood Insurance Act of 1968

and the Flood Disaster Protection Act of 1973.

The community based FIS reports prior to 1979 were prepared for the Federal Insurance Administration (FIA). In 1979, an executive order merged the FIA into the newly formed Federal Emergency Management Agency (FEMA). Reports from that date forward were prepared for FEMA.

The May 17, 2005 FIS (FEMA, 2005) was prepared to include the incorporated communities within Rockingham County in a countywide FIS. Information on the authority and acknowledgments for each jurisdiction included in the 2005 countywide FIS, as compiled from their previously printed FIS reports, is shown below.

Atkinson, Town of: The hydrologic and hydraulic analyses for the FIS report dated April 2, 1993, were prepared by the U.S. Geological Survey (USGS) for the Federal Emergency Management agency (FEMA), under Inter-Agency Agreement No. EMW-88-E-2738, Project Order No. 4. That work was completed in August 1991. The hydrologic and hydraulic analyses for Island Pond were taken from the FIS for the Town of Derry (FEMA, 1981). The hydrologic and hydraulic analyses for Bryant Brook were taken from the FIS for the Town of Plaistow (FEMA, April 1981).

Brentwood, Town of: The hydrologic and hydraulic analyses for the FIS report dated October 15, 1980, were prepared by the Soil Conservation Service (SCS) for the Federal Insurance Administration (FIA), under Inter-Agency Agreement No. IAA-H-17-78. That work was completed in May 1979. The hydrologic and hydraulic analyses for the FIS report dated May 4, 2000, were prepared by the USGS for FEMA, under Inter-Agency Agreement No. EMW-97-1A-0155, Project Order No. 1. That work was completed in June 1998.

Derry, Town of: The hydrologic and hydraulic analyses for the FIS report dated April 15, 1980, were prepared by Anderson-Nichols and Company, Inc., for the FIA, under Contract No. H-3989. That work was completed in March 1978.

Epping, Town of: The hydrologic and hydraulic analyses for the FIS report dated October 15, 1981, were performed by the SCS for FEMA, under Inter-Agency Agreement No. IAA-H-17-78, Project Order No. 15. That work was completed in September 1979.

Exeter, Town of: The hydrologic and hydraulic analyses for the FIS report dated November 17, 1981, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in May 1980.

Fremont, Town of: The hydrologic and hydraulic analyses for the FIS report dated June 19, 1989, represent a revision of the original analyses prepared by the SCS for FEMA, under Inter-Agency Agreement No. IAA-H-17-78, Project Order No. 15. The work for the original analyses was completed in May 1979. The hydrologic and hydraulic analyses for Spruce Swamp were prepared by Dewberry & Davis LLC, under agreement with FEMA. That work was completed in June 1988.

Greenland, Town of: The hydrologic and hydraulic analyses for the FIS report dated May 17, 1989, were performed by the SCS for FEMA, under Inter-Agency Agreement No. EMW-86-E-2225, Project Order No. 01. That work was completed in September 1987

Hampstead, Town of: The hydrologic and hydraulic analyses for the FIS report dated June 16, 1993, were prepared by the USGS for FEMA, under Inter-Agency Agreement No. EMW-88-E-2738, Project Order No. 4. That work was completed in August 1991. The flooding information for Island Pond was taken from the FIS for the Town of Derry (FEMA, 1981).

Hampton, Town of: The hydrologic and hydraulic analyses for the FIS report dated July 3, 1986, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in January 1984.

Hampton Falls, Town of: The hydrologic and hydraulic analyses for the FIS report dated October 15, 1981, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in April 1980.

Kingston, Town of: The hydrologic and hydraulic analyses for the FIS report dated April 15, 1992, were prepared by the USGS for FEMA, under Inter-Agency Agreement No. EMW-87-E-2548, Project Order No. 1A. That work was completed in July 1989.

- Londonderry, Town of: The hydrologic and hydraulic analyses for the FIS report dated May 5, 1980, were prepared by Anderson-Nichols & Company, Inc., for the FIA, under Contract No. H-3989. That work was completed in March 1978.
- New Castle, Town of: The hydrologic and hydraulic analyses for the FIS report dated August 5, 1986, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in April 1984.
- Newfields, Town of: The hydrologic and hydraulic analyses for the FIS report dated June 5, 1989, were prepared by the SCS for FEMA, under Inter-Agency Agreement No. EMW-86-E-2225, Project Order No. 01. That work was completed in September 1987.
- Newmarket, Town of: The hydrologic and hydraulic analyses for the FIS report dated May 2, 1991, were prepared by the USGS for FEMA, under Inter-Agency Agreement No. EMW-85-E-1823, Project Order No. 20. That work was completed in August 1989.
- North Hampton, Town of: The hydrologic and hydraulic analyses for the FIS report dated June 3, 1986, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in February 1984. The Village District of Little Boar's Head, which was enrolled on June 27, 2017, is located on the coastal portion of what was formerly a portion of North Hampton.
- Plaistow, Town of: The hydrologic and hydraulic analyses for the FIS report dated October 15, 1980, were prepared by Anderson-Nichols & Company, Inc., for the FIA, under Contract No. H-4589. Approximate flood boundaries for portions of Seaver Brook and several unnamed streams and swampy areas were determined in August 1976, by Michael Baker, Jr. Inc., under contract to the FIA. That work was completed in October 1978.
- Portsmouth, City of: The hydrologic and hydraulic analyses for the FIS report dated November 17, 1981, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in April 1980.

Raymond, Town of:	The hydrologic and hydraulic analyses for the FIS report dated October 15, 1981, were prepared by the SCS for FEMA, under Inter-Agency Agreement No. IAA-H-17-78. That work was completed in September 1979. The hydrologic and hydraulic analyses for the FIS report dated April 15, 1992, were prepared by Rivers Engineering Corporation for FEMA, under Contract No. EMW-89-C-2821, Project Order No. R89508. That work was completed October 1989. The hydrologic and hydraulic analyses for the FIS report dated May 2, 1995, were prepared by Roald Haestad, Inc., for FEMA, under Contract No. EMW-90-C-3126. That work was completed in March 1993.
Rye, Town of:	The hydrologic and hydraulic analyses for the FIS report dated June 17, 1986, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in March 1984.
Salem, Town of:	The hydrologic and hydraulic analyses for the December 1978 FIS report and June 15, 1979, FIRM (hereinafter referred to as the 1979 FIS), were prepared by the U. S. Army Corps of Engineers (USACE), New England District, for the FIA, under Inter-Agency Agreement No. 1AA-H-7-76, Project Order No. 24. That work was completed in August 1977. The hydrologic and hydraulic analyses for the FIS report dated April 6, 1998 were prepared by the U. S. Department of Agriculture, Natural Resources Conservation Service (NRCS), for FEMA, under Contract No. EMW-94-E-4437. That work was completed in September 1995.
Seabrook, Town of:	The hydrologic and hydraulic analyses for the FIS report dated June 17, 1986, were prepared by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. That work was completed in December 1983.
Seabrook Beach Village District:	The hydrologic and hydraulic analyses for the FIS report dated August 5, 1986, were performed during the preparation of the FIS for the Town of Seabrook by Stone & Webster Engineering Corporation for FEMA, under Contract No. H-4772. The Town of Seabrook study was completed in December 1983.

- South Hampton, Town of: The hydrologic and hydraulic analyses for the FIS report dated July 15, 1992, were prepared by the USGS for FEMA, under Inter-Agency Agreement No. EMW-89-E-2997, Project Order No. 5. That work was completed in September 1990.
- Stratham, Town of: The hydrologic and hydraulic analyses for the FIS report dated May 17, 1989, were prepared by the SCS for FEMA, under Inter-Agency Agreement No. EMW-86-E-2225, Project Order No. 1. That work was completed in September 1987.
- Windham, Town of: The hydrologic and hydraulic analyses for the FIS report dated were performed by Anderson-Nichols & Company, Inc., for the FIA, under Contract No. H-3989. That work was completed in March 1978.

The authority and acknowledgments for the Towns of Auburn, Candia, Chester, Danville, Deerfield, East Kingston, Kensington, Newington, Northwood, Nottingham, and Sandown were not available prior to the 2005 countywide study because no FIS reports had been published for those communities.

The 2005 countywide FIS was produced by Dewberry & Davis LLC under agreement with FEMA. The work was effective in May of 2005. The contract required the digital conversion of existing effective FIRMs and Flood Hazard Boundary Maps, and the preparation of a FIS and Digital FIRM (DFIRM) for Rockingham County (All Jurisdictions). No new hydrologic or hydraulic analyses were prepared.

Base map information shown on FIRM panels produced for the 2005 study was derived from USGS Digital Orthophoto Quadrangles (DOQs) produced at a scale of 1:12,000 from photography dated 1998 or later.

The digital FIRM was produced using New Hampshire State Plane Coordinate system, FIPS Zone 2800 Feet, referenced to the North American Datum of 1983 (NAD 83), GRS80 spheroid.

The January 29, 2021 Countywide Revision

The January 29, 2021 countywide revision was prepared by the University of New Hampshire (UNH) for FEMA under Agreement No. EMB-2010-CA-0916 and completed in November of 2019. The study consisted of revisions to the coastal and riverine analyses in 14 contiguous communities located in eastern Rockingham County, including the City of Portsmouth and the Towns of Exeter, Greenland, Hampton, Hampton Falls, New Castle, Newfields, Newington, Newmarket, North Hampton, Rye, Seabrook, Seabrook Beach Village District, and Stratham.

The January 29, 2021 countywide revision FIS includes revisions to detailed riverine studies in the incorporated community of Newmarket, NH within Rockingham County. Information on the authority and acknowledgements for each of these jurisdictions included in this FIS is shown below.

Newmarket, Town of:	The hydrologic and hydraulic analyses for the FIS report dated January 29, 2021, were prepared by the U.S. Geological Survey, New England Water Science Center, for FEMA. That work was completed in November, 2012.
---------------------	--

In addition, the January 29, 2021 countywide revision FIS includes revisions to Zone A study streams on updated panels in the City of Portsmouth and the Towns of Exeter, Greenland, Hampton, Hampton Falls, New Castle, Newfields, Newington, Newmarket, North Hampton, Rye, Seabrook, Stratham, and the Village Districts of Seabrook Beach and Little Boar's Head. The revisions were based on new estimates for the 1% flood discharges and delineating the 1% flood limits on better topography than available at the time of the previous studies. The work was completed in June 2013.

Base map information shown on FIRM panels produced for mainland NH for the 2013 revision was derived from 1-foot resolution orthophotography acquired in April-May, 2010. Base map information shown on FIRM panels produced for the Isles of Shoals in the Town of Rye was derived from 1-meter resolution orthophotography acquired in 2012. The projection used in the preparation of the digital FIRM was New Hampshire State Plane Feet, FIPS Zone 2800, referenced to the North American Datum of 1983 (NAD 83), GRS80 spheroid.

1.3 Coordination

During the early years of the National Flood Insurance Program, Consultation Coordination Officer's (CCO) meetings were held for each jurisdiction in this countywide FIS. An initial CCO meeting was held typically with representatives of FEMA, the community, and the study contractor to explain the nature and purpose of an FIS, and to identify the streams to be studied by detailed methods. A final CCO meeting was held typically with representatives of FEMA, the community, and the study contractor to review the results of the study. Prior to the countywide FIS, the dates of the historical initial and final CCO

meetings held for all jurisdictions within Rockingham County are shown in Table 1, "Initial and Final CCO Meetings."

TABLE 1 – INITIAL AND FINAL CCO MEETINGS

Community Name	Initial CCO Meeting	Final CCO Meeting
Town of Atkinson	August 31, 1991	March 23, 1992
Town of Brentwood	July 15, 1997	*
Town of Derry	March 1976	February 13, 1979

Town of Windham	March 1976	October 16, 1978

**Data not available*

¹ The land area for this community was previously shown as a portion of The Town of North Hampton. It has now been identified as a separate NFIP community. Therefore, the dates for this community were taken from the The Town of North Hampton.

For the 2005 countywide study, letters were sent to all communities within Rockingham County notifying them of the scope of the FIS. Letters were mailed on July 10, 2002, and stated that the effective FIRMs and Flood Hazard Boundary Maps (FHBMs) of these communities would be digitally converted to a format that conforms to FEMA's Digital FIRM (DFIRM) specifications. The letters further stated that no

new hydrologic and hydraulic analyses were prepared. The results of the 2005 countywide study were reviewed at the final CCO meetings held on November 13, 2003, and attended by representatives of the communities, FEMA, Dewberry and Davis LLC, the University of New Hampshire, and the NH Office of State Planning.

For the January 29, 2021 countywide revision, invitations to attend a Risk MAP Discovery Meeting were sent to the 14 subject communities within Rockingham County on August 31, 2011. The invitations included a request to submit pertinent information on local flood risks and hazards to UNH. The meetings were held on September 22, 2011, and were attended by representatives of the communities, UNH, the FEMA Regional Service Center (RSC), FEMA, AECOM, the NH Office of State Planning, and the New Hampshire-Vermont Water Science Center of the U.S. Geological Survey. Prior to the release of the preliminary maps, communities were invited to attend one of a daylong series of Workmap review sessions held on August 1, 2013, and attended by representatives of the communities, the University of New Hampshire, FEMA, AECOM, the NH Office of Energy and Planning (formerly known as the NH Office of State Planning), and the New Hampshire-Vermont Water Science Center of the U.S. Geological Survey. The final CCO meetings were held on May 8, 2014, and attended by representatives of the communities, UNH, FEMA, AECOM, the NH Office of Energy and Planning, and USGS. All problems raised at that meeting were addressed in this study.

2.0 AREA STUDIED

2.1 Scope of Study

This FIS report covers the geographic area of Rockingham County, New Hampshire.

May 17, 2005 Countywide FIS

All or portions of the flooding sources listed in Table 2, "Flooding Sources Studied by Detailed Methods," were studied by detailed methods.

TABLE 2 – FLOODING SOURCES STUDIED BY DETAILED METHODS

Adams Pond	Lamprey River	Squamscott River
Atlantic Ocean	Little Cohas Brook	Taylor Brook (including Ballard Pond)
Beaver Brook	Little River No. 1	Taylor River
Beaver Lake	Little River No. 2	Tide Mill Creek
Black Brook	Little River No. 3	Tributary C to Beaver Brook
Bryant Brook	Lower Ballard Pond	Tributary E to Beaver Lake
Cohas Brook	Lower Beaver Lake	Tributary E to Little Cohas Brook
Country Pond	Meadow Pond	Tributary F to Beaver Lake
Cunningham Brook	Nesenkeag Brook	Tributary G to Beaver Brook
Drew Brook	Nudds Canal	Tributary H to Drew Brook
Dudley Brook	Pickering Brook	Tributary H to Nesenkeag Brook

TABLE 2 - FLOODING SOURCES STUDIED BY DETAILED METHODS - continued

Exeter River	Piscassic River	Tributary J to Black Brook
Flatrock Brook	Piscataqua River	Tributary O to Beaver Brook
Golden Brook	Policy Brook	Tuxbury Pond
Grassy Brook	Porcupine Brook	Upper Ballard Pond
Great Bay	Porcupine Brook Tributary	Upper Beaver Brook
Great Pond	Powwow Pond	Wash Pond
Hornes Brook	Powwow River (Downstream Reach)	Wash Pond Tributary
Hill Brook	Powwow River (Upstream Reach)	West Channel Policy Brook
Hog Hill Brook	Shields Brook	Winnicut River
Hidden Valley Brook	Shop Pond	World End Brook
Island Pond	Spicket River	World End Pond
Kelly Brook		

The 2005 countywide FIS also incorporated the determinations of letters issued by FEMA resulting in map changes (Letter of Map Revision [LOMR], Letter of Map Revision- based on Fill [LOMR-F], and Letter of Map Amendment [LOMA]), as shown in Table 3, "Letters of Map Change."

TABLE 3 – LETTERS OF MAP CHANGE

Community Name	Flooding Source(s)/ Project Identifier	Effective Date	Type
Portsmouth, City of	Pickering Brook/Ocean Road Development Corporation project	October 6, 1999	LOMR
Rye, Town of	Atlantic Ocean/Brown Property shore protection project	February 15, 2001	LOMR
Salem, Town of	West Channel Policy Brook/Powers Builders property	September 15, 1999	LOMR
Epping, Town of	Lamprey River/downstream of Prescott Road bridge	September 7, 1993	BADL

The areas studied by detailed methods were selected with priority given to all known flood hazard areas and areas of projected development and proposed construction.

Numerous flooding sources in the county were studied by approximate methods. Approximate analyses were used to study those areas having a low development potential or minimal flood hazards. The scope and methods of study were proposed to, and agreed upon by, FEMA and the communities in Rockingham County.

For the 2005 countywide study, several areas of approximate flooding were extended to match the approximate flooding across community corporate limits within Rockingham County and across the county boundary from contiguous counties. The delineation involved the use of topographic maps at a scale of 1:24,000 and contour intervals of 10 and 20 feet (U.S. Department of Interior, 1966).

Three “Little Rivers” exist in Rockingham County. For clarification purposes, they have been renamed in the FIS as follows: Little River in the Town of Exeter is Little River No. 1; Little River in the Town of North Hampton is Little River No. 2; Little River in the Town of Plaistow is Little River No. 3. In addition, Tributary D in the Town of Londonderry has been renamed in the FIS as Tributary O to Beaver Brook.

The January 29, 2021 Countywide Revision

The January 29, 2021 countywide revision consisted of revisions to the coastal and riverine analyses in 14 contiguous communities located in eastern Rockingham County. These communities include: Exeter, Greenland, Hampton, Hampton Falls, the Village District of Little Boar’s Head, New Castle, Newfields, Newington, Newmarket, North Hampton, Portsmouth, Rye, Seabrook, Seabrook Beach Village District, and Stratham.

The work performed in these communities consisted of revisions as follows:

- New Atlantic coastal analysis
- Revised Zone AE studies on the Exeter and Lamprey Rivers
- Revisions due to updated topographic data on the Piscataqua River, Great Bay shoreline, Squamscott River, Little River No. 1 (in Exeter), Little River No. 2 (in North Hampton), Pickering Brook, Piscassic River, and the Winnicut River
- New model-backed Zone A studies replaced all existing Zone A streams

The updated topographic data used for the 2013 study was based on LiDAR collected at a 2.0 meter nominal post spacing (2.0m GSD) for approximately 8,200 mi² of coastal areas including parts of Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, and New York, as part of the American Recovery and Reinvestment Act (ARRA) of 2009. The data was collected by Photo Science Inc. in May of 2011. No snow was on the ground and rivers were at or below normal levels. Some areas of the project required 1.0 meter nominal post spacing (1.0m GSD), and a required 9.25cm Vertical Accuracy. The study area was covered by 1.0 meter post spacing LiDAR data and a portion of the contributing drainage area was covered by the 2.0 meter post spacing LiDAR data. A seamless Digital Elevation Model (DEM) at a 10 ft resolution was created combining the above datasets to create a base elevation for the coastal analyses.

For the Isles of Shoals, the LiDAR was available for the northern portion of Star Island only. For the remainder of Star Island, a topographic map with 2-foot contour intervals developed by Ambit Engineering, Inc, in May of 2011, based on information collected in 1916, was digitized and converted to NAVD 88. The topography for the other islands, which are low lying, was taken from USGS 10 meter digital elevation models.

No Letters of Map Revision (LOMRs) were incorporated in the 2013 coastal update.

2.2 Community Description

Rockingham County is located in southeastern New Hampshire. In Rockingham County, there are 37 communities. The Towns of Northwood, Nottingham, and Deerfield are located in the northwestern section of the county. The Towns of Epping, Newmarket, and Newfields are located in the northern section of the county. In the eastern part of the county, lie the City of Portsmouth and the Towns of Newington, Greenland, New Castle, Stratham, Exeter, North Hampton, and Rye. The Seabrook Beach Village District, Village District of Little Boar's Head, and the Towns of Hampton, Hampton Falls, and Seabrook are located in the southeastern part of the county. The Towns of Brentwood and Fremont are located in the center of Rockingham County. In the southern section of the county lie the Towns of Sandown, Danville, Kingston, East Kingston, Kensington, Hampstead, Atkinson, Plaistow, Newton, and South Hampton. In the southwestern section of the county, the Towns of Derry, Londonderry, Windham, and Salem are located. The Towns of Candia, Raymond, Auburn, and Chester are located in the western part of Rockingham County.

Rockingham County is bordered to the north by communities of Strafford County: the Towns of Strafford, Barrington, Lee, Durham, and Dover. To the northeast, the county is bordered by communities of York County, Maine: the Towns of Kittery and Eliot. It is bordered to the northwest by communities of Merrimack County: the Towns of Pittsfield, Epsom, Allenstown, and Hooksett. Rockingham County is bordered to the southwest by communities of Hillsborough County: the City of Manchester and the Towns of Bedford, Merrimack, Litchfield, Hudson, and Pelham. To the south, the county is bordered by the communities of Essex County, Massachusetts: the Cities of Methuen and Haverhill and the Towns of Amesbury and Salisbury. According to the U.S. Census Bureau, the population of Rockingham County was 295,223 in 2010.

The topography of the county is flat coastal plains to the east, gently rolling hills to the south and center, and more hilly terrain to the northwest. The Atlantic coast is characterized by sandy beaches, rocky headlands, wetlands, and offshore reefs and ledges. The development in Rockingham County is primarily residential.

The climate of the county can be classified as modified continental. The average annual temperature is approximately 47 degrees Fahrenheit (U.S. Department of Commerce). The average rainfall of the county is 42 inches per year (FEMA, 1993).

The main flooding sources in Rockingham County are the Atlantic Ocean to the east, Exeter River in the east, Lamprey River in the center, Little Cohas Brook in the west, and Beaver Brook in the south.

2.3 Principal Flood Problems

Past history within the county indicates that major floods occur during the spring, fall, and winter seasons. Some of the most severe flooding occurs in early spring as

a result of snowmelt and heavy rains in conjunction with ice dams. Less frequently, flooding occurs later in the year as a result of localized thunderstorms or hurricanes. The largest of these floods occurred in March 1896, March 1936, March 1977, January 1978, March 1983, April 1987, July 1934, March 1936, and April 1987. No estimate of peak flow was available for the 1896 flood, but the 1936, 1977, and 1987 flows were estimated at 5,490, 5,000, and 7,500 cfs, respectively.

Low-lying areas are subject to periodic flooding caused by overflows of the Lamprey River, Exeter River, and Squamscott River. The most severe flooding occurs in early spring as a result of snowmelt and heavy rains. In the past, portions of Prescott Road along Lamprey River have flooded nearly every year. The 1989 replacement of the Prescott Road Bridge over the Lamprey River should help alleviate this condition. During the April 1987 flood, up to two feet of water covered portions of Harriman Hill Road. Old Manchester Road and Main Street were also affected by flooding of the Lamprey River in 1987.

The low-lying areas along the Atlantic coast are subject to the periodic flooding and wave attack that accompany northeasters and hurricanes. The majority of these storms cause damage only to low coastal roads, boats, and seawalls. Occasionally, a major storm accompanied by strong onshore winds and high tides results in surge and wave activity that cause extensive property damage and erosion. Some of the more significant storms include those of December 1909, December 1959, February 1972, and February 1978. The recurrence intervals for these storms were 160 years, 15 years, 10 years, and 70 years, respectively. Other significant storms occurred in the vicinity of North Hampton in November 1945, November 1963, November 1968, and November 1969. These storms damaged harbors, marinas, and commercial and residential developments along the flood-prone coastline (FEMA, City of Portsmouth, 1981). Other more recent noteworthy storms causing significant flooding in the area have included May 2006, April 2007, and March 2010.

During spring runoff periods, the Exeter River frequently flooded roads on the south side of the Town of Exeter, including Court Street, Crawford Avenue, and Portsmouth Avenue. A USGS surface-water discharge station was active on the Exeter River at the Haigh Road Bridge in Brentwood during a 1996 storm and recorded a peak discharge of 3,060 cfs. This event had a recurrence interval of approximately 100 years. Additional areas were flooded by the Exeter River, due to rainfall associated with hurricanes in 1938 and 1954. The area on the north side of the Exeter River in Tib's Grove is subject to occasional backwater flooding from Phillips dam in the Town of Brentwood.

The major portion of the Spicket River floodplain lies between the Arlington Mill Reservoir and the Massachusetts State line. Because of its flat gradient and the numerous swamps and lakes in the watershed, peak flows and stages on the Spicket River are a function of high-volume rainfall.

The middle reach of Policy Brook between Rockingham Park Boulevard and Pleasant Street is subject to periodic flooding due to its flat gradient and the many restrictions caused by inadequately sized pipes and culverts.

The Squamscott River periodically floods the Swasey Parkway and other low-lying areas during unusually high tides. In the past, within the Town of Greenland, little significant damage has occurred in these areas, however, due to the general absence of buildings and other structures.

Low-lying areas adjacent to Great Bay are subject to periodic flooding. Little significant damage occurs in these areas, however, due to the general absence of buildings and other structures.

Areas along Pickering Brook are subject to flooding. Present damage potential is slight due to absence of structures in affected marshes. However, future flood damage could be significant if development upstream of State Route 151 is allowed to lower the road elevation of 31 feet. This road crest is the emergency spillway necessary if debris clogs the only culvert through the dam-like road fill. The extensive upstream beaver action and by-products of urbanization could be sources of flood-creating debris.

Extensive flooding in the low-lying areas surrounding the Powwow Pond system occurred in March 1983. During the flood, elevations on Great Pond peaked at approximately 2 feet above the dam crest. According to records at the New Hampshire Department of Water Resources, this is the maximum recorded elevation for Great Pond.

Minor damage to Cuba Road frequently occurs due to flooding of the Piscassic River. This flooding usually occurs during March and April during spring rains and snowmelt. Floods occurring during other seasons are often associated with debris clogging culverts. Due to the natural and manmade hydraulic structures along the Piscassic River, and the number of beavers in the watershed, collection of debris generally compounds flooding.

Flooding problems have occurred in the past and may be expected to occur in the future at the undersized culvert at State Route 125 crossing of Kelly Brook. Such situations can create backwaters of depth sufficient to inundate extensive areas of land.

2.4 Flood Protection Measures

The State of New Hampshire provides concrete seawalls and stone revetments to protect coastal highways. The USACE built shoreline protection structures at Wallis Sands State Beach (U.S. Department of the Interior, 1962) and at Hampton Beach (New England River Basins Commission, 1980). The Town of Rye maintains a small portion of the waterfront barrier in the southern end of town. Other protective coastal structures were constructed and are maintained by the local municipalities and private property owners to satisfy their individual requirements and financial capabilities. These structures include such backshore protection as timber and steel sheet piles, bulkheads, stone revetments, concrete seawalls, and pre-cast concrete units (U.S. Army Corps of Engineers, 1971). Limited financial resources sometimes result in less than adequate protection.

A breakwater located in the Town of Rye that is maintained by the USACE provides some protection for Little Harbor. There are some small-scale protective structures maintained by private homeowners that satisfy individual requirements.

A protective breakwater is located on the north shore of the Hampton Harbor inlet. It extends approximately 1,000 feet southeast into the Atlantic Ocean and protects the mouth of both Hampton and Seabrook Harbors from wave action.

The Water Division of the New Hampshire Department of Environmental Services controls the Trickling Falls Dam at the outlet of Powwow Pond and the dam at the outlet of Great Pond. During the fall and early winter, flash boards are removed from these dams and the ponds are lowered to provide extra storage capacity for spring runoff. There are also extensive low-lying areas surrounding the Powwow Pond system. These areas provide natural storage that serves to reduce flood peaks.

Dams at the outlet of Powwow Pond and Great Pond in East Kingston provide some flood protection in areas upstream of South Hampton; however, the effect on peak discharge in South Hampton is not significant (U.S. Department of the Interior, 1962). Likewise, the dam at Tuxbury Pond provides negligible flood protection.

In the Town of Stratham, zoning has been established to prevent development within 150 feet of the Squamscott River and 100 feet of major freshwater streams.

There is a levee separating sewage treatment plant stabilization lagoons from the Squamscott River. FEMA specifies that all levees must have a minimum of 3 feet freeboard against 1 percent annual chance flooding to be considered a safe flood protection structure. The levee has a nominal crest elevation of 14 feet, yielding a 6-foot freeboard which meets FEMA freeboard requirements. There are also several small dams within the town. However, they do not significantly alter flood flows.

The numerous swampy areas and small ponds within Rockingham County provide natural storage that serves to reduce flood peaks.

Newmarket has no existing or proposed flood control structures. During extreme flood events, floodwaters from the Lamprey River overflow State Route 108 upstream in Durham and are diverted into the Oyster River basin. These overflows or diversions reduce peak flood discharges of the Lamprey River before it reaches the Town of Newmarket. During a 1 percent annual chance flood, diversions to the Oyster River basin reduce flood peaks in Newmarket by approximately 20 percent (FEMA, 1991).

3.0 ENGINEERING METHODS

For the flooding sources studied in detail in the county, standard hydrologic and hydraulic study methods were used to determine the flood hazard data required for this FIS. Flood events of a magnitude which are expected to be equaled or exceeded once on the average

during any 10-, 50-, 100-, or 500-year period (recurrence interval) have been selected as having special significance for floodplain management and for flood insurance rates. These events, commonly termed the 10-, 50-, 100-, and 500-year floods, have a 10-, 2-, 1-, and 0.2-percent chance, respectively, of being equaled or exceeded during any year. Although the recurrence interval represents the long term average period between floods of a specific magnitude, rare floods could occur at short intervals or even within the same year. The risk of experiencing a rare flood increases when periods greater than 1 year are considered. For example, the risk of having a flood which equals or exceeds the 100-year flood (1-percent chance of annual exceedance) in any 50-year period is approximately 40 percent (4 in 10), and, for any 90-year period, the risk increases to approximately 60 percent (6 in 10). The analyses reported herein reflect flooding potentials based on conditions existing in the county at the time of completion of this FIS. Maps and flood elevations will be amended periodically to reflect future changes.

3.1 Riverine Hydrologic Analyses

Hydrologic analyses were carried out to establish the peak discharge-frequency relationships for the flooding sources studied in detail affecting the county.

For each community within Rockingham County that has a previously printed FIS report, the hydrologic analyses described in those reports have been compiled and are summarized below.

Pre-countywide Analyses

Discharge-frequency data for the flooding sources studied by detailed methods were determined from equations based on multiple-regression analyses of data from USGS gaged sites in New Hampshire and adjacent areas of bordering states (U.S. Department of the Interior, 1978). The equations contain the independent variables basin drainage area, main-channel slope, and a precipitation intensity index.

No stream gages have been operated in the Powwow River Basin. To calculate the 1 percent annual chance frequency flood discharges, three separate reports were consulted (U.S. Department of the Interior, 1975; U.S. Department of the Interior, 1978; and U.S. Department of the Interior, 1983). The three reports document techniques that can be used to estimate flood peaks on rural basins in Maine, New Hampshire, and Massachusetts. In each of the reports, regression equations were used to relate flood-peak discharges to basin characteristics such as drainage area, stream slope, basin storage, and precipitation. The Powwow River basin is located near coastal New Hampshire in an area close to both Massachusetts and Maine. Data from this portion of New Hampshire was included in each of three studies and as a result, information from all of the reports could be appropriate for use.

Flood discharges were computed using equations from each of the three reports and the results were carefully reviewed. Analysis indicated that use of the equation documented in the report for Massachusetts would be most appropriate (U.S. Department of the Interior, 1983). The Massachusetts report is the most current of the

three and it used a larger data base. Most importantly, the area studied in the report was divided into three separate regions and regression equations were calculated for each. One of the three zones was the eastern or coastal area, the region in which the Powwow River basin is located. Regression equations developed for the eastern region were specific to the coastal type of watershed. The Massachusetts equations have also been used in two other studies in the Powwow River basin: East Kingston, New Hampshire, and Amesbury, Massachusetts (FEMA, April 1986; FEMA, 1982).

Due to the excessive amount of natural storage in the Powwow Pond system, adjustment of the peak discharge was required. Using techniques documented in a USGS report, a basin lag time and an inflow hydrograph were computed with a peak discharge of 1,240 cfs (U.S. Department of the Interior, 1983). The resultant hydrograph was routed through the Powwow Pond system using the Modified Puls Method (Linsley, R. K., et al., 1982). The Modified Puls method is based on a form of the continuity equation in which for any time period, average inflow less average outflow equals change in storage within the system. Based on this analysis, the resultant 1 percent annual chance flood frequency outflow from Powwow Pond is 850 cfs. Drainage area ratios were used to compute 1 percent annual chance flood frequency peak discharges at alternate points in the Powwow Pond system as a function of the outflow from Powwow Pond.

Due to the absence of gaged data, the principal source of data for defining discharge-frequency relationships for all detailed streams in Windham (Beaver Brook, Golden Brook, Flatrock Brook, and Hidden Valley Brook) was regional discharge-frequency equations developed by Manuel Benson. These regional equations relate topographical and precipitation characteristics to streamflow (U.S. Department of the Interior, 1962).

The Squamscott River, Exeter River, Little River No. 1, Little River No. 2, and Winnicut River are ungaged. The 10-, 2-, and 1-percent annual chance flood discharges were based on regional peak discharge and frequency formulas developed by the USGS (U.S. Department of the Interior, 1978). A separate evaluation of these formulas was performed and found to be applicable to the Exeter region. In addition, the formulas were expanded and an equation was developed to predict the 0.2 percent annual chance flood discharge. The USGS formulas predict discharges based on the parameters of watershed drainage area, main channel slope, and rainfall intensity.

Hydrologic analysis of the 1 percent annual chance flood was performed for Dudley Brook. Discharge for the 1 percent annual chance flood was based on a U.S. Water Resources Council log-Pearson Type III frequency analysis of gage data at the USGS gage no. 01073600 on Dudley Brook near the Town of Exeter, which has 23 years of record (1962 -1985) and a drainage area of 12.1 square miles (U.S. Water Resources Council, 1976). Discharges from the gage analysis were transferred to stream stations removed from the gage by the formula:

$$Q / Q_g = (A/A_g)^{0.75}$$

Where Q is the discharge at the different specific site locations, Q_g is the discharge

at the USGS stream gage, and A and Ag are the drainage areas at the specific site and at the USGS stream gage, respectively.

Discharges for the Little River No. 3, Kelly Brook, and Bryant Brook were developed by combining the results of regional flood frequency equations with discharge values transposed from gaged basins in the region, which are similar in size and characteristics, to those studied. The regional equations, developed from regression analysis of gaging records for eastern Massachusetts using basin parameters to estimate flood peaks, were applied at several points along each stream (U.S. Geological Survey, 1977). USGS gage no. 0107300 on the Oyster River in Durham was used to transpose discharges to the Little River No.3. This gage has a period of record of 43 years and a drainage area of 12.1 square miles. The USGS gage no. 01073600 on Dudley Brook near Exeter was used to transpose discharges to Kelly Brook and Bryant Brook. The transposition was carried out using the formula as shown above.

The principal sources of data for defining discharge-frequency relationships for detailed study streams in Londonderry (Beaver Brook, Black Brook, Cohas Brook, Little Cohas Brook, Nesenkeag Brook, Shields Brook, Tributary C to Beaver Brook, Tributary E to Little Cohas Brook, Tributary H to Nesenkeag Brook, Tributary J to Black Brook, Tributary O to Beaver Brook, and Upper Beaver Brook) were the regional equations developed by Manuel Benson of the USGS. These regional equations relate topographical and precipitation characteristics to stream flow (U.S. Department of the Interior, 1962).

Discharges for Hidden Valley Brook were derived by comparing values predicted by regional equations and discharge-frequency relationships based on a log-Pearson Type III analysis (U.S. Water Resources Council, 1976) for the gages in the vicinity on Stony Brook (USGS Gage No. 093800) and on Dudley Brook (USGS Gage No. 073600) (U.S. Department of the Interior, 1976).

Discharge-frequency data for Hog Hill Brook, Wash Pond Tributary, Hill Brook, Wash Pond, and Shop Pond were determined from equations based on multiple-regression analyses of data from USGS gaged sites in New Hampshire and adjacent areas bordering states (U.S. Department of the Interior, 1978). The equations contain the independent variable basin drainage area, main-channel slope, and a precipitation intensity index.

Discharge values for the Exeter River in the Town of Brentwood were obtained from the previous FISs for the Towns of Brentwood and Exeter (FEMA, 1980; FEMA, May 1982). Peak discharges for the Exeter River were obtained from the Town of Exeter FIS, enacted on November 17, 1981, and were based on regional peak discharge and frequency formulas developed by the USGS and expanded to predict the 0.2 percent annual chance flood discharge (U.S. Department of the Interior, 1978). Peak discharges for the Exeter River obtained from the original FIS for the Town of Brentwood were based on a flow rate per unit area relationship with a USGS surface-water discharge station on the Lamprey River (FEMA, 1981).

For the Exeter River in the Town of Raymond, only the peak 1 percent annual chance flood return period discharge was computed. The peak discharge at the Blueberry Hill Road bridge was available from NHDOT (U.S. Department of the Interior, 1962). The value was computed using regionally developed peak flows for more frequent storms in combination with a methodology involving a probability distribution to produce the 1 percent annual chance flood peak discharge. The peak 1 percent annual chance flood discharge computed by Rivers Engineering Corporation using methodology used as part of the FISs for other New Hampshire communities was not significantly different from the value computed by the NHDOT (U.S. Water Resources Council, 1977). The NHDOT value was adjusted to other location on the Exeter River based on the ratio of the drainage areas.

Gaging stations on the Lamprey River, located approximately 9 miles north of the Exeter River, and on Dudley Brook, a tributary of the Exeter River, were the principal sources of data for determining discharge-frequency relationships for the Exeter River in the Town of Fremont. The gages have been in operation since 1934 and 1962, respectively. Values for the 10-, 2-, 1-, and 0.2-percent annual chance flood peak discharges were obtained from a log-Pearson Type III distribution of annual peak flow data.

Flows for the various frequencies were transformed to a flow rate per unit area and plotted versus drainage area on log-log paper. A straight line was drawn through the pairs of flow-drainage area coordinates computed for the gages. Flows for drainage areas of the Exeter River at various locations in Fremont were taken from the plot.

A check on the procedure described above was made at the Fremont-Brentwood corporate limits by application of regional relationships developed in USGS Water-Supply Paper 1580-B and Water Resources Investigations 78-47 (U.S. Department of the Interior, 1962; U.S. Department of the Interior, 1978). The regression analyses developed in these reports relate peak discharge to drainage area, channel slope and rainfall intensity. The method in Water-Supply Paper 1580-B also considers indices for surface water area, January temperature, and orographic effect.

Since the Piscassic River is ungaged, discharge-frequency data for this flooding source was developed using the USGS Water Resources Investigation Report, WRI 78-47, a synthetic runoff procedure that relies on regionalized climatological data coupled with the individual stream physical characteristics for input (U.S. Department of the Interior, 1978).

For Beaver Brook, Cunningham Brook, Drew Brook, Taylor Brook, Tributary E to Beaver Lake, Tributary F to Beaver Lake, Tributary G to Beaver Lake, Tributary H to Drew Brook, and Tributary O to Beaver Brook, the principal source of data for defining discharge-frequency relationships was the regional discharge-frequency equations developed by the USGS (U.S. Department of the Interior, 1962). These regional equations relate topographical and precipitation characteristics to streamflow. Due to the extensive upstream channel and pond storage and flatter slopes, discharges for the Homes Brook-Shields Brook watershed were derived using

a regional discharge-frequency equation based on streams with similar characteristics (U.S. Department of the Interior, 1974).

Discharges for Beaver Brook were modified due to the storage effects of Beaver Lake. Golden Brook was modified due to the storage effects of Cobbetts Pond and Moeckel (Simpson)-Rock Ponds. Taylor Brook was modified due to the storage effects of Ballard Pond. A reservoir routing using a numerical iteration method (Viessman, Warren J., et al., 1972) was performed on Beaver Lake and Island Pond. The results of this routing were used to adjust the discharges of Beaver Brook and Taylor Brook and to establish the water-surface elevations of Beaver Lake for the 10-, 2-, 1-, and 0.2-percent annual chance floods. The results of the reservoir routing performed on Cobbetts Pond were used in conjunction with the results of Benson's equation to adjust the discharges of Golden Brook between Tributary C and Moeckel (Simpson)-Pond. Below Moeckel (Simpson) Pond, the discharges were adjusted using the results of the reservoir routing performed on Moeckel (Simpson)-Rock Ponds.

The principal source of data for defining the discharge-frequency relationships for the Lamprey River was the USGS gaging station located in Durham, which had been operating since 1934. Values of the 10-, 2-, 1-, and 0.2-percent annual chance flood peak discharges were obtained from a log-Pearson Type III distribution of annual peak flow data (U.S. Department of the Interior, 1967).

Discharge-frequency estimates for areas above the stream gage were developed using a regional relationship developed in a USGS report (U.S. Department of Agriculture, 1979). The regression analysis developed in this report relates peak discharge to drainage area, channel slope, rainfall intensity, surface storage, January temperature, and orographic influences. The flow estimates developed by the USGS were estimated by multiplying the ratio of discharge based on gage data to that based on the USGS method for the gaged area time the discharge developed by the USGS at locations within Raymond.

Flood flows for the Lamprey River were determined by using regional equations for peak discharges applicable to the area (Southeastern New Hampshire Regional Planning Commission, 1974). This method combines basin and climatic characteristics through specific regression equations to yield discharges for the 10-, 2-, and 1-percent annual chance floods. Peak discharges for the 0.2 percent annual chance flood return period storm were based on an equation developed as an extension of the methodology developed by the USGS and used for prediction of the peak 0.2 percent annual chance flood return period discharge as part of the FISs for other New Hampshire communities (U.S. Water Resources Council, 1977; Southeastern New Hampshire Regional Planning Commission, 1974). Peak flows computed by use of the regional equations were determined to be more appropriate for the Lamprey River in Raymond than a transposition of peak flows computed at the gaging station downstream in Durham. As described below, the transposition of flows from the gage produced peak flows in Raymond that did not adequately reflect the magnitude of flooding experienced by the community.

There are no continuous records of discharges on the Spicket River. A peak discharge for the March 1968 flood was computed and reported by the USGS for the Spicket River at a dam located approximately 1.5 miles below the Salem, New Hampshire-Methuen, Massachusetts, town line. A peak discharge of 1,440 cubic feet per second (cfs) was computed at this site, which has a total drainage area of 73.8 square miles.

A gaged stream in the region with similar hydrologic characteristics is the Parker River, located approximately 15 miles southeast of Salem. This river has 30 years of discharge records for a contributing watershed of 21.6 square miles. Discharge frequencies for the Spicket River were estimated using peak discharge frequency data for the Parker River. Frequencies for the Parker River were developed from historical flow data using the log-Pearson Type III statistical distribution (U.S. Water Resources Council, 1976, Bulletin 15). The frequencies for the Spicket River were then developed by multiplying the Parker River flows by the ratio of the known 1968 peak discharges on both streams. Discharges at other locations along the Spicket River were derived by multiplying the adopted discharges at the dam in Methuen by a factor equal to the ratio of the drainage areas to the 0.7 exponential power.

Over the years, Policy Brook has been modified by the installation of two long conduits under and adjacent to Rockingham Park. Conduit A extends from just upstream of Pleasant Street to just above the brook's second crossing of the Boston and Maine Railroad and State Route 28. It passes under the horse barn area of the race track. Conduit B and an excavated section of open ditch run along the railroad and bypass the second railroad/State Route 28 crossing. This bypass was installed to reduce the flooding of a mobile home park just to the east of State Route 28.

The installation of the bypass results in Policy Brook having two channels, an East Channel and a West Channel in this area. The West Channel (conduit-ditch) carries all of the flows from upper Policy Brook during non-flood periods as the second railroad/State Route 28 crossing has been partially blocked.

Flood discharges for the lower reaches of Policy Brook, its East Channel, and Unnamed Brook were developed by estimating the mean annual peak flows based on an appraisal of existing culvert size on the streams and the sluggish hydrologic character of the watersheds. Rarer flood flows for the brooks were determined as multiples of the mean annual flows by use of the "Bigwood-Thomas" type flood formula as well as by rainfall frequency comparisons (U.S. Geological Survey, 1955). Both the Technical Release No. 20 (TR-20) and the Technical Release No. 55 (TR-55) models were used to develop the 1 percent annual chance flood discharges at various points in the watershed (U.S. Department of Agriculture, 1992; U.S. Department of Agriculture, 1986). TR-20 is a synthetic rainfall runoff procedure that relies on regionalized climatological data coupled with the individual stream physical characteristics for input (U.S. Department of Agriculture, 1983). Drainage areas, land uses and times of concentration were computed using USGS quadrangle coverage. A rainfall of 6.5 inches in a 24-hour period was used to produce the unit hydrographs.

The peak discharge for the April 1987 flood at the USGS gage at Packers Falls was 7,500 cfs. The 1 percent annual chance flood discharge at the gage was determined in Section 3.1 to be 7,300 cfs. The 1987 flood was therefore slightly greater than the 1 percent annual chance flood. Peak flood elevations that occurred during the 1987 flood were identified and surveyed in the field by the study contractor. The 1 percent annual chance flood profile for Lamprey was based on these elevations and data available for Durham (FEMA, 1991).

A TR-55 analysis was used to develop discharges on Porcupine Brook and Porcupine Brook Tributary.

For the analysis of the West Channel and the upper reaches of Policy Brook, temporary flood storage in Canobie Lake, in the large, flat area between Pleasant Street and South Policy Road and in Rockingham Park at the outlet of Conduit A were included in the TR-20 model. The area above Pleasant Street, because of its size and the limited capacity of Conduit A, is especially effective in reducing flood flows.

Since Pickering Brook is not gaged, discharge-frequency data for this stream were developed using TR-20.

For World End Pond, both the outlet channel and the constricted downstream road crossings (Lawrence Road and Farm Road) were modeled. For the 1 percent annual chance flood, the road crossings were found to control the upstream water levels and these stage discharge relationships were used in the TR-20 model.

Only the 1 percent annual chance flood elevations have been determined for stillwater elevations for Wash Pond, Country Pond, Great Pond, Piscataqua River, World End Pond, and Shop Pond. No adjustments to computed "Stillwater Elevations" were made to account for changes in storage in Wash Pond and Shop Pond. These changes in storage were considered insignificant.

Discharges for approximate study streams were also developed using Manuel Benson's regional discharge-frequency equations (U.S. Department of the Interior, 1962).

2005 Countywide Analyses

No hydrologic analyses were conducted for the 2005 countywide study.

The January 29, 2021 Countywide Revision

For the January 29, 2021 countywide revision, hydrologic analyses were carried out to establish peak discharge-frequency relationships for each flooding source studied by approximate methods in the communities studied, and for the flooding sources studied

in detail affecting the towns of Exeter and Newmarket. Discharges for the 1-percent-annual-chance recurrence interval for all approximate study streams in these communities were determined using regression equations found in Olson, S.A., 2009, Estimation of flood discharges at selected recurrence intervals for streams in New Hampshire, U.S. Geological Survey Scientific Investigations Report 2008-5206.

Hydrologic analyses for the Lamprey River (Newmarket, NH) was based on a log-Pearson Type III frequency analysis of the stream gage data at the USGS stream gage no. 01073500 at Packers Falls at Durham, NH which has 77 years of record (1934 – 2011) and a drainage area of 185 square miles. Based on a recently completed Lamprey River watershed study at the University of New Hampshire (Scholz, 2011), it was assumed that 20% of Lamprey River flood flow is diverted to the Oyster River watershed via La Roche and Longmarsh Brooks.

Discharges from the stream gage analysis were transferred to stream locations removed from the stream gage by the formula:

$$Q/Q_g = (A/A_g)^{1.0}$$

Where Q is the discharge at the different specific site location, Q_g is the discharge at the USGS stream gage, and A and A_g are the drainage areas at the specific site and at the USGS stream gage, respectively.

A summary of the drainage area-peak discharge relationships for all of the streams studied by detailed methods is shown in Table 4, “Summary of Discharges.”

3.2 Riverine Hydraulic Analyses

Analyses of the hydraulic characteristics of flooding from the source studied were carried out to provide estimates of the elevations of floods of the selected recurrence intervals. Users should be aware that flood elevations shown on the FIRM represent rounded whole-foot elevations and may not exactly reflect the elevations shown on the Flood Profiles or in the Floodway Data tables in the FIS report. For construction and/or floodplain management purposes, users are encouraged to use the flood

elevation data presented in this FIS in conjunction with the data shown on the FIRM.

Locations of selected cross sections used in the hydraulic analyses are shown on the Flood Profiles (Exhibit 1). For stream segments for which a floodway was computed (Section 4.2), selected cross section locations are also shown on the FIRM (Exhibit 2).

On detailed study streams, all bridges, dams, and culverts were field surveyed to obtain elevation data and structural geometry.

Flood profiles were drawn showing the computed water-surface elevations for floods of the selected recurrence intervals.

The hydraulic analyses for this FIS were based on unobstructed flow. The flood elevations shown on the profiles are thus considered valid only if hydraulic structures remain unobstructed, operate properly, and do not fail.

For each community within Rockingham County that has a previously printed FIS report, the hydraulic analyses described in those reports have been compiled and are summarized below.

Precountywide Analyses

Cross sections and geometry of hydraulic structures were obtained from field surveys conducted during the 1990 field season by the study contractor. Cross-section extensions were based on information contained on USGS topographic maps (U.S. Department of the Interior, 1985, et cetera; U.S. Department of the Interior, 1981).

For the Town of Raymond FIS report dated April 15, 1992, cross sections for the Exeter and Lamprey Rivers were obtained from field surveys and interpolation from USGS topographic maps (U.S. Department of the Interior, September 1981). Elevation data and structural geometry for bridges and culverts on both rivers were obtained from a combination of record drawings and field survey. The Prescott Road bridge at the downstream end of the Lamprey River in the Town of Raymond was under construction at the time the revised hydraulic analyses were performed. For this reason, drawings issued for construction were used to obtain hydraulic data for this bridge.

The portions of the cross sections within the limits of the channel were obtained by field survey by Kenneth A. LeClair Associates (Kenneth A. LeClair Associates, 1978). Overbank cross-sectional data were read from topographic maps at a scale of 1:2,400 (State of New Hampshire, 1970). Bridge plans were utilized to obtain elevation data and structural geometry for bridges over the streams studied in detail. Where plans were unavailable or out-of-date, bridges were also surveyed.

Cross sections for the backwater analyses of the detailed study streams were located at close intervals above and below bridges in order to compute the significant

backwater effects of these structures in the developed areas. In long reaches between structures, appropriate valley cross sections were also surveyed.

For Hog Hill Brook, cross sections and geometry of hydraulic structures were obtained from field surveys conducted during the 1988 field season by the USGS. Cross-section extensions and basin characteristics were based on information contained on USGS topographic maps at a scale of 1:25,000 and 1:24,000 with contour intervals of 3 meters and 10 feet (U.S. Department of the Interior, 1985, et cetera). For Island Pond and Bryant Brook, cross sections for the backwater analyses were located at close intervals above and below bridges in order to compute the significant backwater effects of these structures in developed areas. In long reaches between structures, appropriate valley cross sections were also surveyed.

Cross-section data for the Spicket River were taken from a USACE floodplain report (U.S. Army Corps of Engineers, 1975). For Policy Brook and Unnamed Brook, cross-section data were obtained by field survey.

For the Powwow Pond/Powwow River, cross sections and elevations and structural geometry of hydraulic structures were obtained from field surveys conducted by the study contractor during the 1987 field season. Upper-end extensions of cross sections and storage areas were based on information contained on USGS topographic maps (U.S. Department of the Interior, 1981).

Water-surface elevations of floods of the selected recurrence intervals were computed using the WSPRO step-backwater computer program (Federal Highway Administration, 1990; U.S. Department of the Interior, 1989).

Water-surface elevations of floods of the selected recurrence intervals for Beaver Brook, Exeter River, Little River No. 1, Shields Brook, Homes Brook, Taylor Brook, Drew Brook, Cunningham Brook, Tributary 0 to Beaver Brook, Tributary E to Beaver Lake, Tributary F to Beaver Lake, Tributary G to Beaver Brook, and Tributary H to Nesenkeag Brook were developed using the USACE HEC-2 step-backwater computer program (U.S. Army Corps of Engineers, 1973; U.S. Army Corps of Engineers, 1977). Elevation data and structural geometry for bridges and culverts on both rivers were obtained from a combination of record drawings and field survey. The Prescott Road bridge at the downstream end of the Lamprey River in the Town of Raymond was under construction at the time the revised hydraulic analyses were performed. For this reason, drawings issued for construction were used to obtain hydraulic data for this bridge. Water-surface elevations for Spicket River of floods of the selected recurrence intervals were computed using the USACE HEC-2 step-backwater computer program (U.S. Army Corps of Engineers, 1976).

Water-surface elevations of floods of the selected recurrence intervals were computed for all detailed study streams in the community through use of the USACE HEC-2 step-backwater computer program (U.S. Army Corps of Engineers, 1977).

Water-surface elevations of floods of the selected recurrence intervals for Hog Hill

Brook, Pickering Brook, the Lamprey River, Piscassic River, West Channel Policy Brook, Porcupine Brook, and portions of the Exeter River in Fremont were computed using the SCS WSP-2 step-backwater computer program (U.S. Department of Agriculture, 1979; U.S. Department of Agriculture, 1976; U.S. Department of Agriculture, 1993).

The 1 percent annual chance flood elevations for Hog Hill Brook were computed by applying WSPRO step-backwater computer model (Federal Highway Administration, 1986; Federal Highway Administration, 1990). Starting water-surface elevations for the 1 percent annual chance flood discharge on Hog Hill at the downstream side of Haverhill Road bridge at the Salem-Atkinson corporate limits were determined using the slope/area method (Federal Highway Administration, 1986; Federal Highway Administration, 1990). Starting water-surface elevations for Bryant Brook were determined by the slope/area method. Flood profiles were drawn showing computed water-surface elevations for floods of the selected recurrence intervals.

Starting water-surface elevations for Hog Hill Brook were based on computations of elevation versus discharge at Wadleigh Falls in the Town of Lee.

Starting water-surface elevations for the Lamprey River were taken from the lower reaches of the river in the FIS report dated May 2, 1995 (FEMA, 1995). Flood profiles were drawn showing computed water-surface elevations for floods of the selected recurrence intervals.

The starting water-surface elevation for the downstream reach of the Powwow River was determined by rating the dam at the outlet of Lake Gardiner in Amesbury, Massachusetts using the weir equations referenced above. The starting water-surface elevation for Grassy Brook was computed by a slope conveyance calculation (Federal Highway Administration, 1986; U.S. Department of the Interior, 1989). The stream slope was determined from field surveys.

Starting water-surface elevations for the Exeter River in the Town of Raymond, Winnicut River, Little River No. 3, Kelly Brook, and Bryant Brook were determined by the slope/area method. Water-surface elevations of floods of the selected recurrence intervals were computed for the Little River, Kelly Branch, and Bryant Brook in the study area through use of the USACE HEC-2 step-backwater computer program (U.S. Army Corps of Engineers, 1976).

Starting water-surface elevations for the Exeter River in the Town of Exeter and Little River No. 2 were determined using critical depth. Starting water-surface elevations for the Exeter River in the Town of Fremont were based on computations of elevation versus discharge at Phillips Dam and for the Exeter River in the Town of Brentwood, starting water-surface elevations were taken from a previously studied downstream portion of the river (FEMA, October 15, 1980, FIS report; and April 15, 1981, FIRM).

Starting water-surface elevations for the Little River No. 1 were determined using

normal pool elevation for the Exeter River in the Town of Exeter for the 10 percent annual chance flood and the slope/area method for the 2-, 1-, and 0.2-percent annual chance floods.

Starting water-surface elevations for the 1 percent annual chance flood discharges on Hill Brook at the downstream side of the State Route 111 bridge and Shop Pond Outlet at the downstream side of Mills Shore Drive were computed using the slope-conveyance method (Federal Highway Administration, 1986 and 1990). The starting water-surface elevation for the 1 percent annual chance flood discharge on Wash Pond Tributary was the 1 percent annual chance flood elevation for Wash Pond.

For Golden Brook and Hidden Valley Brook, starting water-surface elevations were determined through normal depth analysis. For Flatrock Brook, the starting water-surface elevation was determined from a rating curve developed at the outlet of Shadow Lake.

Starting water-surface elevations for Beaver Brook were obtained from the Londonderry FIS and Hudson FIS (U.S. Department of Housing and Urban Development, 1978); Shields Brook and Tributary D from the Derry FIS (U.S. Department of Housing and Urban Development, unpublished); and Nesenkeag Brook from the Litchfield FIS (U.S. Department of Housing and Urban Development, 1977). For Black Brook, Tributary E to Beaver Lake, Tributary J to Black Brook, Tributary C to Beaver Brook, Upper Beaver Brook, Cohas Brook, Tributary H to Drew Brook, Dudley Brook, Island Pond, and Shields Brook studied by detailed methods, starting water-surface elevations were determined by normal-depth analyses.

Starting water-surface elevations for Tributary E to Little Cohas Brook and Tributary F to Beaver Lake were obtained from the Beaver Lake flood elevations, and starting water-surface elevations for Drew Brook and Taylor Brook were obtained from Island Pond flood elevations. Starting water-surface elevations for Tributary H to Nesenkeag Brook were obtained from the Drew Brook flood profile because these streams have concurrent flood peaks.

Starting water-surface elevations for the Spicket River at the dam at Arlinpon Mills Reservoir were determined from the standard Weir Formula $Q=CLH^3$. At the southern corporate limit, the 1 percent annual chance flood elevation was taken from the USACE floodplain report (U.S. Army Corps of Engineers, 1975). The starting water-surface elevation for the 10-, 2-, and 0.2-percent annual chance floods exceeded the capacity of the 60-inch culvert, and it was assumed that the water level of 124 feet (also top of the culvert) would be the ponding level for all frequency events.

Starting water-surface elevations for West Channel Policy Brook and Porcupine Brook were taken from the 1978 FIS for the Town of Salem, and a Master Drainage Study done by Weston & Sampson Engineers, Inc., respectively (U.S. Department of Housing and Urban Development, Federal Insurance Administration, 1978;

Weston and Sampson Engineers, Inc., 1988). A rating curve for World End Pond was computed by backwater analysis of flows through the Lawrence Road-Farm Road culverts.

The starting water-surface elevations for the Piscassic River were determined by computing critical depths at the Piscassic Ice Pond Dam.

Pickering Brook was studied by detailed methods in the Town of Greenland FIS, dated May 17, 1989, from a point 2,400 feet upstream of its confluence with Great Bay extending up to the corporate limits for the Town of Greenland. Starting water-surface elevations for Pickering Brook were determined by assuming critical depth at the upstream normal high tide limits of Great Bay. Water-surface elevations of floods of the selected recurrence intervals were computed through the use of the SCS WSP2 step-backwater computer program. Pickering Brook was also studied by detailed methods using the HEC-RAS hydraulic model by a LOMR effective October 6, 1999, in the Town of Portsmouth, New Hampshire, from a point approximately 2,482 feet upstream of the corporate limits for the City of Portsmouth to a point approximately 2,733 feet upstream of the corporate limits. The hydraulic analysis for Pickering Brook was extended downstream of the LOMR effective October 1999, using the HEC-RAS hydraulic model, to the corporate limits of the City of Portsmouth. The starting water-surface elevations were set at the 1 percent annual chance flood water-surface elevation at the corporate limits for the Town of Greenland.

Elevations of MacCallen Dam and the State Route 108 bridge in Newmarket were obtained from field surveys conducted by the study contractor. The 1 percent annual chance flood elevations for the Lamprey River upstream from MacCallen Dam were based upon high-water elevation data available for the April 1987 flood and data available from the FIS for the Town of Durham (FEMA, 1991).

The 1 percent annual chance flood elevation for Tuxbury Pond was determined by rating the dam at the outlet of the pond. The rating curve for the dam was determined by applying the appropriate flow over weir equations documented in a USGS publication (U.S. Department of the Interior, 1967). This elevation was also used as the starting water-surface elevation for the upstream reach of the Powwow River.

The valley portions of the cross-section data for all detailed study streams were obtained photogrammetrically by James W. Sewall Company (James W. Sewall Company, 1977); the below-water portions were obtained by field measurement by Thomas F. Moran, Inc. (Thomas F. Moran, Inc., 1977). Bridge plans were utilized to obtain elevation data and structural geometry. All bridges for which plans were unavailable or out of date were surveyed.

In those areas where the analysis indicated supercritical flow conditions, critical depth was assumed for the flood elevation because of the inherent instability of supercritical flow.

Approximate methodologies for Hidden Valley Brook include hydrologic and

hydraulic calculations based on the detailed study and field investigation.

Along certain portions of Piscassic River, a profile base line is shown on the maps to represent channel distances as indicated on the flood profiles and floodway data tables.

The 1 percent annual chance flood for portions of both the Spicket River and Policy Brook was approximated, using information from an SCS Flood Prone Area Map (U.S. Department of Agriculture, 1974).

The 1 percent annual chance flood on several smaller streams was approximated using the FHBM for the Town of Salem as a guide (U.S. Department of Housing and Urban Development, 1977).

The 1 percent annual chance flood elevation for Powwow Pond/Powwow River downstream from the Boston and Maine Railroad bridge was determined by rating the dam (Trickling Falls Dam) at the outlet of the pond. For the purposes of this analysis, it was assumed that a total of 1 foot of stop logs in the gates of the dam have been removed, a practice commonly used by the Water Division of the New Hampshire Department of Environmental Services. The rating curve for the dam was determined by applying appropriate flow over weir equations documented in a USGS publication (U.S. Department of the Interior, 1967).

The 1 percent annual chance flood elevation for Powwow Pond/Powwow River upstream from the Boston and Maine Railroad bridge is controlled by the dam at the outlet of the pond and the constriction caused by the bridge opening. The flood elevation was determined by treating the opening as a culvert and passing the 1 percent annual chance flood discharge through it by applying appropriate formulas contained in a USGS publication (U.S. Department of the Interior, 1968).

The 1 percent annual chance flood elevation for Powwow Pond/Powwow River upstream from New Boston Road is influenced by the constriction caused by the twin culverts at the crossing. The flood elevation was determined by passing the 1 percent annual chance flood discharge through the twin culverts by applying appropriate formulas contained in a USGS publication (U.S. Department of the Interior, 1968). Road overflow at the site was computed by applying a step-backwater computer model (Federal Highway Administration, 1986).

The 1 percent annual chance flood elevation for Country Pond is the same as determined for Powwow Pond/Powwow River upstream from New Boston Road. Backwater from the culverts at New Boston Road extends into Country Pond. The bridge at the outlet of Country Pond does not constrict the flow sufficiently to increase elevations in the pond. To verify this fact, a step-backwater run was made through the reach (Federal Highway Administration, 1986).

The 1 percent annual chance flood elevation for Great Pond is influenced by backwater caused by the culvert under State Route 125 and Main Street bridge

just downstream from the outlet. The dam at the outlet of the lake has only a small head and is drowned out during floods. Elevations upstream from State Route 125 were determined by passing the 1 percent annual chance flood discharge through the culvert by applying appropriate formulas contained in a USGS publication (U.S. Department of the Interior, 1968). The elevation upstream from State Route 125 and the 1 percent annual chance flood discharge were routed through the bridge opening of the State Route 111 crossing and into the pond using a step-backwater model (Federal Highway Administration, 1986).

Roughness factors (Manning's "n") used in the hydraulic computations were chosen by engineering judgment and were based on field observations of the streams and floodplain areas. Roughness factors for all streams studied by detailed methods are shown in Table 6, "Manning's "n" Values."

2005 Countywide Analyses

No hydraulic analyses were conducted for the 2005 countywide study.

The January 29, 2021 Countywide Revision

The Lamprey River was studied by detailed methods in the town of Newmarket from the MacCallen Dam to the upstream corporate limit for the Town of Newmarket, NH.

For the Town of Newmarket, the Lamprey River channel and structural cross section data (elevation, northing and easting) were obtained from USGS field surveys and Wright-Pierce, Inc. field surveys. The overbank portion of the cross section data for the Lamprey River was derived from the 2011 coastal LiDAR dataset described above.

Cross sections for the backwater analyses of the detailed study streams were located at close intervals above and below bridges in order to compute the significant backwater effects of these structures in the developed areas. In long reaches between structures, appropriate valley cross sections were also obtained from within channel surveys and from LiDAR on the overbanks.

Water-surface elevations of floods of the selected recurrence intervals were computed for the detailed study streams using U.S. Army Corps of Engineers HEC-RAS (version 4.1.0) step-backwater computer program (U.S. Army Corps of Engineers, January 2010). In those areas where the analysis indicated supercritical flow conditions, critical depth was assumed for the flood elevation because of the inherent instability of supercritical flow.

Starting water-surfaces for the Lamprey River were determined through computation of critical depth at the MacCallen Dam in Newmarket.

The Lamprey River HEC-RAS flood model was calibrated to the USGS streamgage 01073500 data and to the peak high-water mark data collected by the USGS along the Lamprey River after the April 2007 flood.

As in the pre-countywide analyses, roughness factors (Manning's "n") used in the coastal study hydraulic computations were chosen by engineering judgment and were

based on field observations of the streams and floodplain areas. Roughness factors for the Lamprey River are also shown in Table 6, “Manning’s “n” Values”.

TABLE 6 – MANNING’S “n” VALUES

Stream	Channel “n”	Overbank “n”
Beaver Brook	0.020-0.055	0.040-0.100

Winnicut River	0.020-0.050	0.070
World End Brook and Pond	0.020-0.060	0.100

No Manning's "n" factors were assigned for computations on Catletts Creek since its flood hazard is dependent upon valley restrictions with their associated storage and not upon conveyance.

For the January 29, 2021 countywide revision, water-surface profiles for Zone A basic studies and for Zone AE detailed studies were computed through the use of the USACE HEC-RAS computer program (USACE 2010). Water surface profiles were computed for the 1-percent-annual-chance storm for the Zone A basic studies and for the 0.2, 1, 2, and 10-percent-annual chance storms for the Zone AE detailed studies.

The Zone A basic studies used the computer program Watershed Information SystEm (WISE) as a preprocessor to HEC-RAS (Watershed Concepts, 2008). WISE combined geo-referenced data from the terrain model and miscellaneous shapefiles (such as streams and cross sections). The WISE program was used to generate the input data file for HEC-RAS. Then HEC-RAS was used to determine the flood elevation at each cross section of the modeled stream. No floodway was calculated for the Zone A basic studies.

3.3 Coastal Analyses

Pre-countywide Analyses

The coastal analyses for the 2013 coastal study update supercede coastal analyses previously completed, except on the Piscataqua River, Great Bay, and the Squamscott River estuary.

Hydraulic analyses of the inland propagation of the coastal storm surge were performed for the Piscataqua River, Great Bay, and the Squamscott River estuary system using the 1-D Model. The 1-D Model is based on the hydrodynamic equations of motion and conservation of mass. The estuary system was divided into grids, with each cross section divided into areas of conveyance and storage. Cross-section data were obtained from U.S. Coast and Geodetic Survey nautical charts. The most downstream grid was located at the mouth of the Piscataqua River, while the most upstream grid was located just below the Chestnut Hill Avenue bridge over the Squamscott River in Exeter. A Chezy friction coefficient of 70 was used throughout the estuary. Wind effects were not included. Both upstream and downstream boundary conditions, the former being the function of freshwater inflow and the latter the sum of the astronomical tide and surge components, were specified initially and for the duration of the storm. Sensitivity analyses were performed for selected storm and hydraulic parameters.

2005 Countywide Analyses

No coastal analyses were conducted for the 2005 countywide study.

The January 29, 2021 Countywide Revision

The 10-, 2-, 1- and 0.2 percent annual chance stillwater elevations for the coastal areas within Rockingham County were derived from FEMA (2008) “Updating Tidal Profiles for the New England Coastline” updating the U.S. Army Corps of Engineers 1988 tidal gage profiles developed for the entire New England Coastline. The New England Tidal Flood Profiles, from Bergen Point, New York, to the Maine border with Canada, were updated by conducting new flood frequency analyses of long-term tide gage records available from the NOS and USACE. Parametric probability distributions were fit to the tide gage data using the method of L moments. The suite of probability distributions applied to the gage records included the original Pearson Type III distribution to enable comparisons between the old tidal flood profiles and the results from the new analyses. The tidal flood profiles were updated using the best fitting probability distribution, as determined by goodness-of-fit criteria.

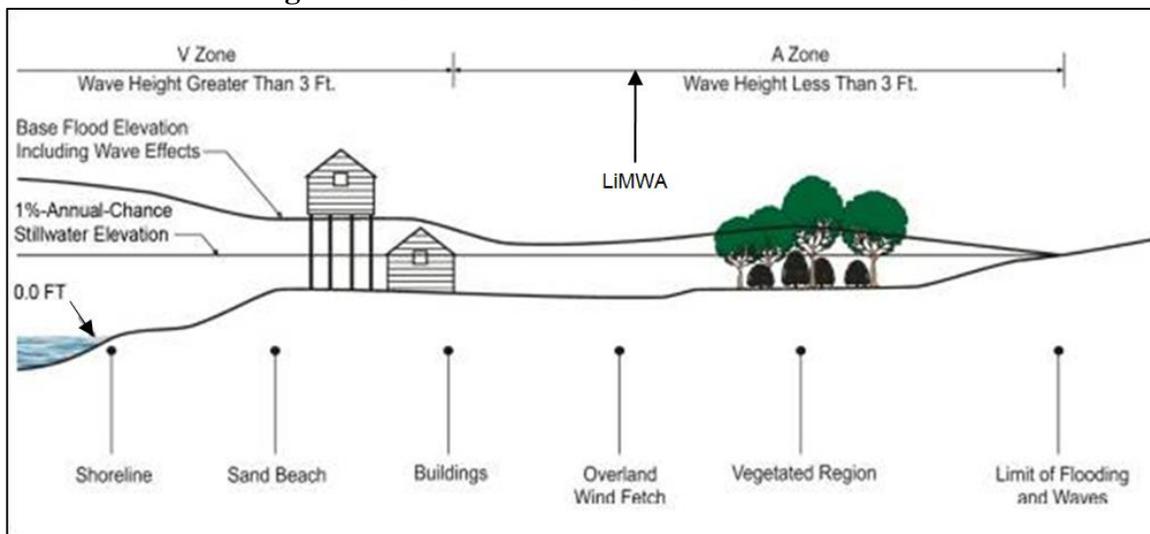

Areas of coastline subject to significant wave attack are referred to as coastal high hazard zones. The USACE has established the 3-foot breaking wave as the criterion for identifying the limit of coastal high hazard zones (U.S. Army Corps of Engineers, June 1975; U.S. Army Corps of Engineers, 1973). The 3-foot wave has been determined as the minimum size wave capable of causing major damage to conventional wood frame or brick veneer structures. Damages to structures from wave heights between 1.5

and 3 feet are similar to, but less severe than, those in areas where wave heights are greater than 3 feet. These areas have been designated as areas of moderate wave action, and areas up to the Limit of Moderate Wave Action (LiMWA) have been mapped on the FIRM.

Overland wave height analyses were performed along each transect using the FEMA Wave Hazard Analysis for Flood Insurance Studies (WHAFIS) model to determine wave heights and corresponding wave crest elevations for the areas inundated by the tidal flooding. A wave runup analysis was performed to determine the height and extent of runup beyond the limit of tidal inundation. The results of these analyses were combined into a wave envelope, which was constructed by extending the wave runup elevation seaward to its intersection with the wave crest profile.

Figure 1, "Transect Schematic," illustrates a profile for a typical transect along with the effects of energy dissipation and regeneration on a wave as it moves inland. This figure shows the wave crest elevations being decreased by obstructions, such as buildings, vegetation, and rising ground elevations, and being increased by open, unobstructed wind fetches. Figure 3 also illustrates the relationship between the local still water elevation, the ground profile and the location of the Zone V/Zone A boundary.

Figure 1: Coastal Transect Schematic

Deepwater wave characteristics used as starting wave conditions to the wave setup, overland and wave runup analyses were derived from the USACE Wave Information Studies (WIS) hindcast stations, located offshore the New Hampshire coast. The USACE website (<http://wis.usace.army.mil/>) provides an extreme wave analysis performed on the yearly maxima (1980-1999) at the selected stations used as the source of the 1-percent annual chance event significant wave height. The wave period associated with the 1-percent wave significant wave height was derived using a wave steepness factor of 0.035, the average wave steepness of tropical and extra-tropical events. Such wave conditions were applied to all transects facing the Atlantic Ocean shoreline. Starting wave conditions for the New Castle area, located along the Piscataqua River, were derived using a limited fetch approach within the WHAFIS model.

FEMA guidelines for Zone V mapping define H_s as the significant wave height or the

average over the highest one third of waves and T_s as the significant wave period associated with the significant wave height. Mean wave conditions are described as:

$$\bar{H} = H_s \times 0.626$$

$$\bar{T} = T_s \times 0.85$$

where \bar{H} is the average wave height of all waves and \bar{T} is the average wave period.

Wave heights and wave runup were computed along transects which were located perpendicular to the shoreline. The transects were located with consideration given to the physical and cultural characteristics of the land so that they would closely represent conditions in their locality. Transects were spaced close together in areas of complex topography and dense development. In areas having more uniform characteristics, the transects were spaced at larger intervals. It was also necessary to locate transects in areas where unique flooding existed and in areas where computed wave heights varied significantly between adjacent transects.

The transect profiles were obtained using topographic and bathymetric data from various sources.

The NOS Bathymetric data was acquired over several years by various agencies. The data is compiled and distributed by NOAA NOS. The bathymetric data for this project is a compilation of data acquired in 1947, 1950, 1953, 1954, 1955, 1997, 2000 and 2005. The NOS states that the accuracy of the data acquired before 1965 is difficult to determine but data acquired after 1965 must comply with standards set forth in the NOS Hydrographic Surveys Specifications and Deliverables. All bathymetric data received from the NOS has been found to meet these specifications. The data was received in Mean Low Datum and converted to NAD_1983_StatePlane_New Hampshire_FIPS_1600_Feet for use in this project.

LiDAR was collected at a 2.0 meter nominal post spacing (2.0m GSD) for approximately 8,200 mi² of coastal areas including parts of Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, and New York, as part of the American Recovery and Reinvestment Act (ARRA) of 2010. No snow was on the ground and rivers were at or below normal levels. Some areas of the project required 1.0 meter nominal post spacing (1.0m GSD), and a required 9.25cm Vertical Accuracy. The area covered by the Piscataqua/Salmon Falls study area was covered by 1.0 meter post spacing LiDAR data and a portion of the contributing drainage area was covered by the 2.0 meter post spacing LiDAR data. A seamless Digital Elevation Model (DEM) at a 10 ft resolution was created combining the above datasets to create a base elevation for the coastal analyses.

Figures 2a and 2b, “Transect Location Map”, illustrate the location of the transects for the coastal study area.

Dune erosion was applied as per standard FEMA (2007) Guidelines and Specifications for Flood Hazard Mapping Partners methodology and VE Zones were mapped up to the extent of the Primary Frontal Dune (PFD).

Nearshore wave-induced processes, such as wave setup and wave runup, constitute a greater part of the combined wave envelope than storm surge due to location exposed to ocean waves. The Direct Integrated Method (FEMA, 2007) was used to determine wave setup along the coastline.

Wave height calculations used in this study follows the methodology described in the FEMA (2007) Guidelines and Specifications for Flood Hazard Mapping Partners. Overland wave analyses were performed along each transects using the FEMA WHAFIS 4.0 model.

Wave runup was computed in agreement with the FEMA (2005) “Procedure Memorandum No. 37” that recommends the use of the 2% wave runup for determining base flood elevations. For mild sandy beaches, Runup 2.0 was employed using mean wave conditions. Along armored shorelines, wave runup was determined using the Technical Advisory Committee for Water Retaining Structures (TAW) method (van der Meer, 2002). The Shore Protection Manual (SPM) Method was applied in cases of wave runup on vertical structures. For wave run-up at the crest of a slope that transitions to a plateau or down-slope, run-up values were determined using the “Methodology for wave run-up on a hypothetical slope” as described in the FEMA (2007) Guidelines and Specifications for Flood Hazard Mapping Partners. In areas where the wave runup overtopped the crest of a structure/bluff, the wave runup elevation was capped at 3 ft above the structure crest.

The transect data for Rockingham County is presented in Table 7, “Transect Descriptions,” which describes the location of each transect. In addition, Table 8 provides the 1-percent annual chance stillwater, wave setup and maximum wave crest elevations for each transect along the coastline.

Figure 2A: Transect Location Map – North

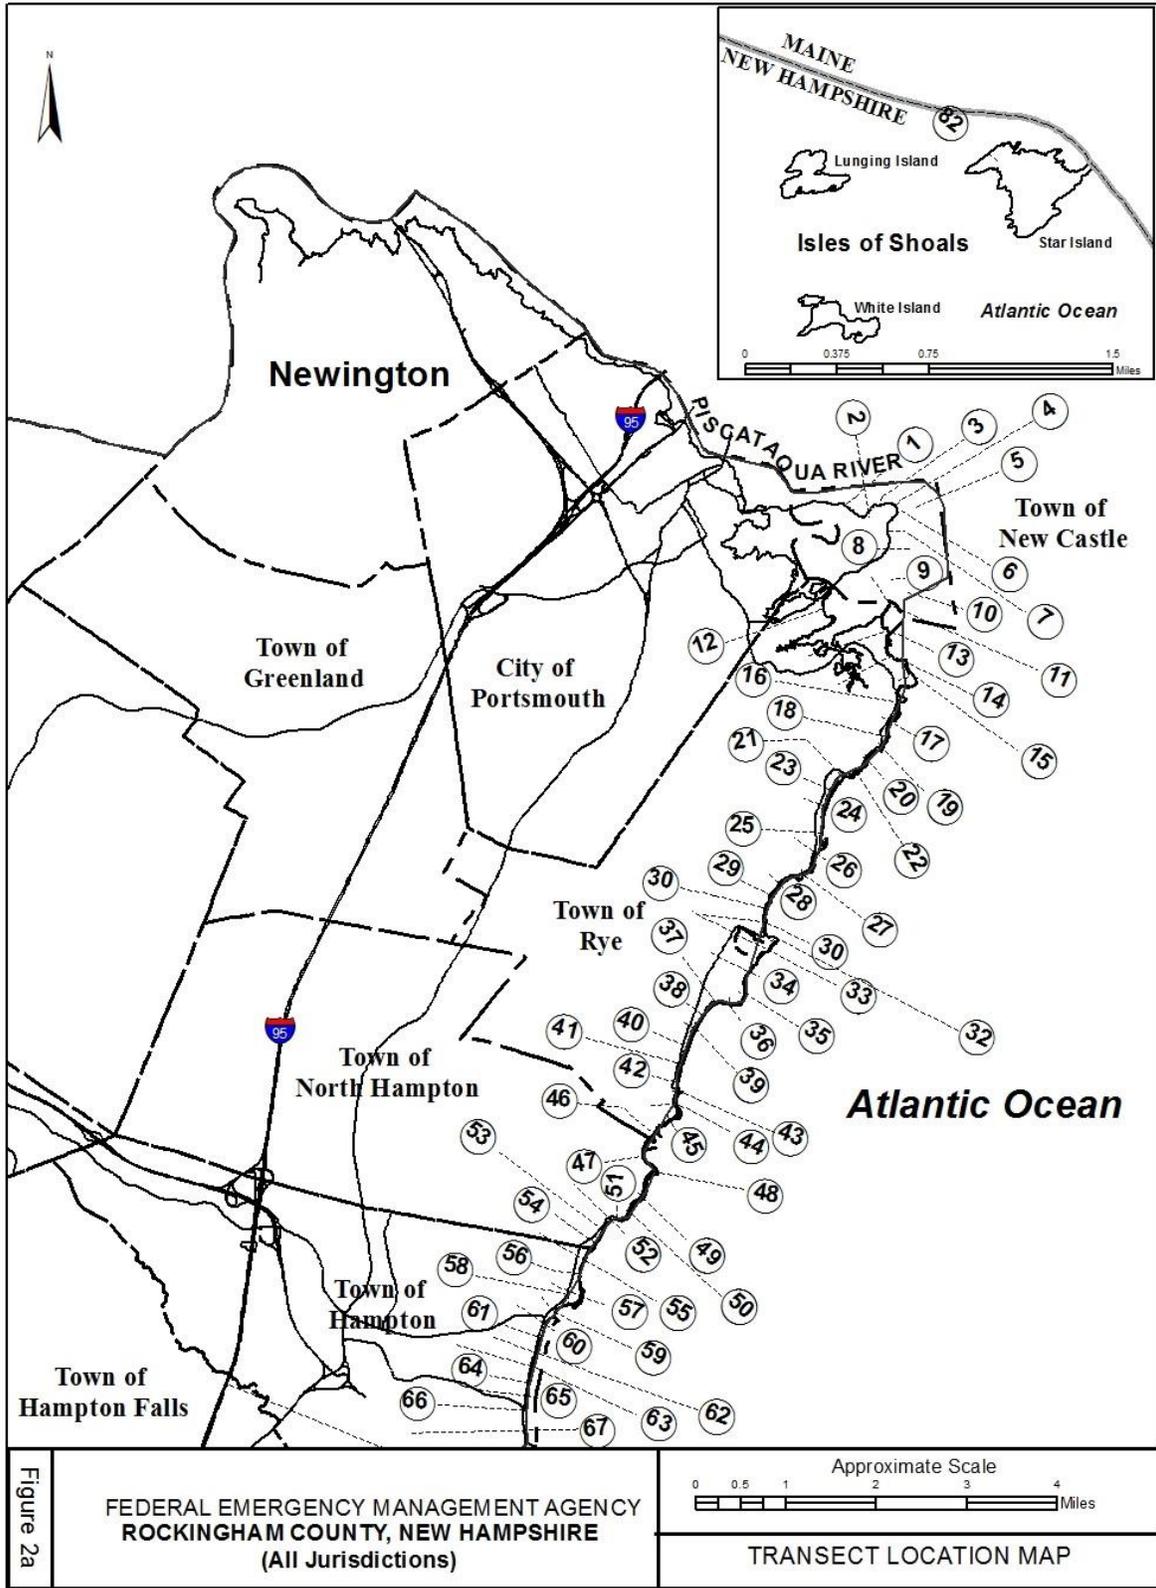

Figure 2B: Transect Location Map – South

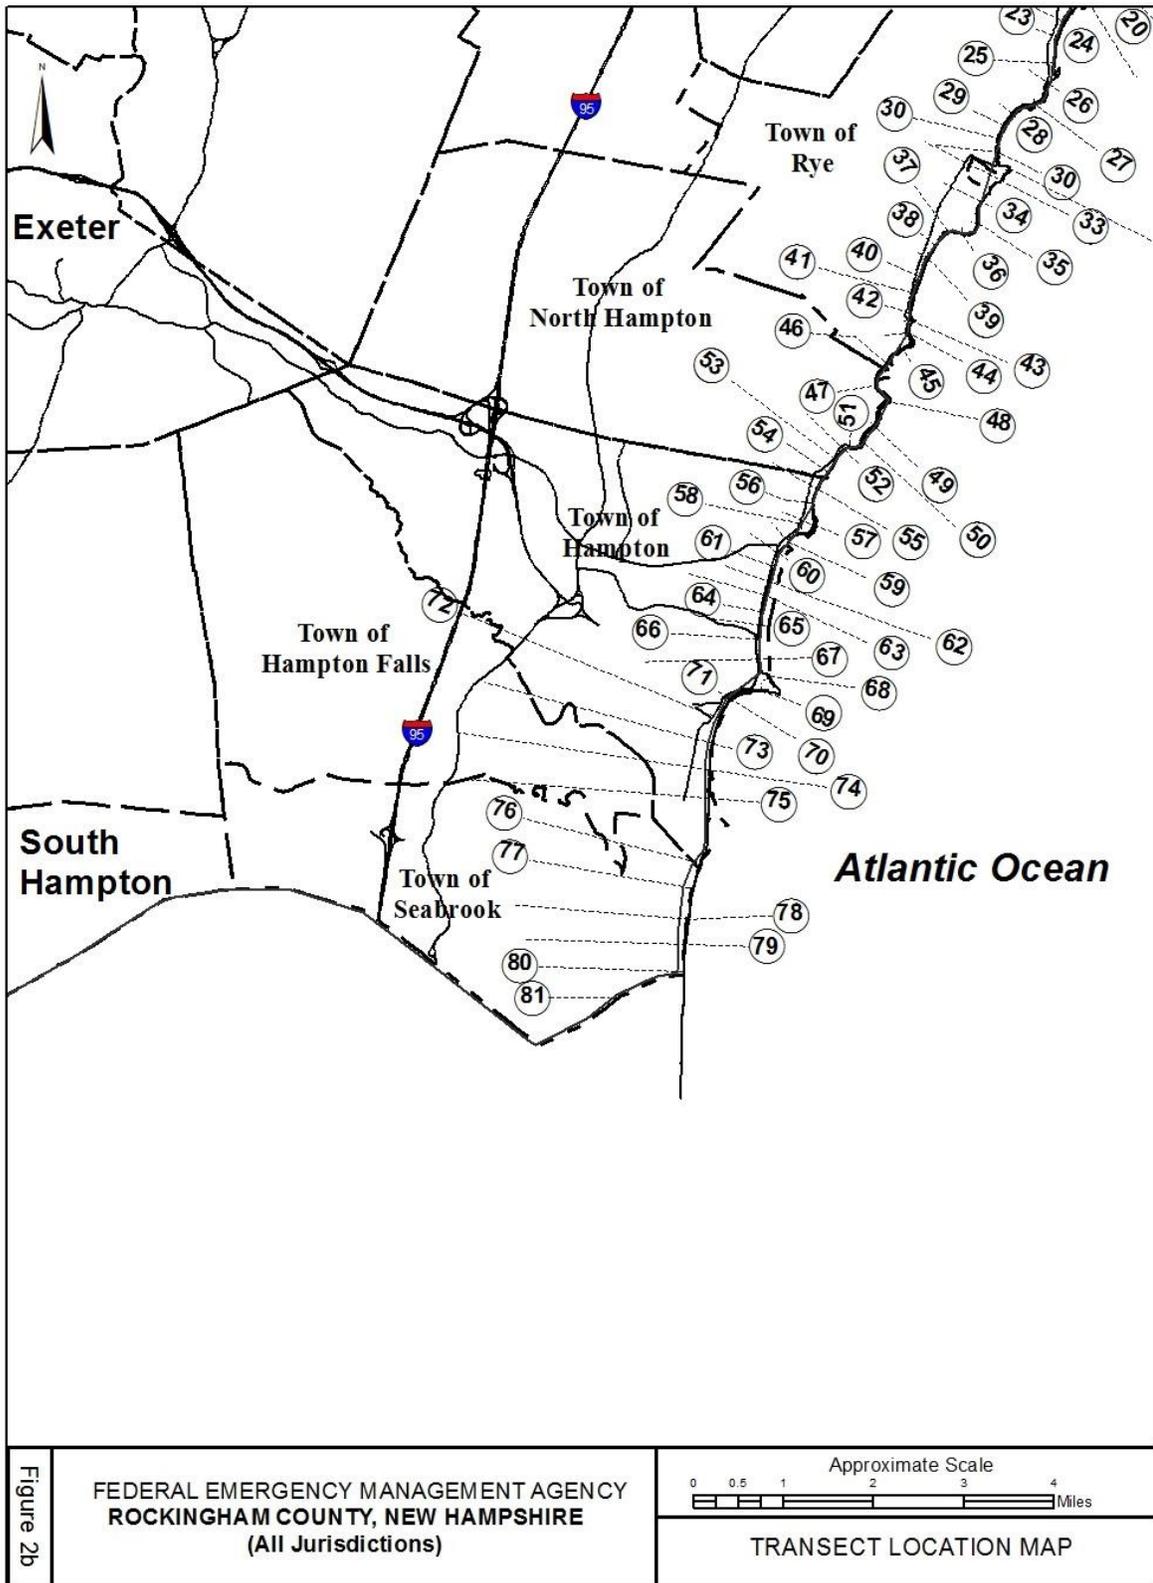

TABLE 7 – TRANSECT DESCRIPTIONS

Transect	Location	Elevation (feet NAVD88*)		
		1-Percent Annual Chance Stillwater	Wave Setup	Maximum 1-Percent Annual Chance Wave Crest ¹
1	On the Atlantic Ocean coastline, on the N side of New Castle, approximately 820 feet NE of the intersection of SR 1B (Portsmouth Ave) and Riverview Rd at N 43.0727390°, W -70.7241097°	8.36	0.66	12.37
2	On the Atlantic Ocean coastline, on the N side of New Castle, approximately 410 feet N of the intersection of SR 1B (Cranfield St) and Neals Pit Ln at N 43.071050°, W -70.718230°	8.36	0.47	11.5
3	On the Atlantic Ocean coastline, on the NE side of New Castle, approximately 100 feet E of the intersection of Elm Court and Piscataqua St at N 43.072602°, W -70.718230°	8.36	0.59	11.82
4	On the Atlantic Ocean coastline, on the NE side of New Castle, approximately 220 feet NE of the intersection of Walbach St. and Piscataqua St., at N 43.071906°, W -70.714279°	8.36	0.6	11.93

*Due to map scale limitations, base flood elevations shown on the FIRM represent average elevations for the zones depicted.

**North American Vertical Datum of 1988

¹Including stillwater elevations and effects of wave setup

²Wave runup elevation

Users of the FIRM should also be aware that coastal flood elevations are provided in Table 5 “Summary of Coastal Stillwater Elevations” in this report. If the elevation on the FIRM is higher than the elevation shown in this table, a wave height, wave runup, and/or wave setup component likely exists, in which case, the higher elevation should be used for construction and/or floodplain management purposes.

As defined in the July 1989 *Guidelines and Specifications for Wave Elevation Determination and V Zone Mapping*, the coastal high hazard area (Zone VE) is the area where wave action and/or high velocity water can cause structural damage (*Guidelines and Specifications for Wave Elevation Determination and V-Zone Mapping*, FEMA, 1989). It is designated on the FIRM as the most landward of the following three points:

- 1) The point where the 3.0 ft or greater wave height could occur;
- 2) The point where the eroded ground profile is 3.0 ft or more below the maximum runup elevation; or
- 3) The primary frontal dune as defined in the NFIP regulations.

These three points are used to locate the inland limit of the coastal high hazard area to ensure that adequate insurance rates apply and appropriate construction standards are used, should local agencies permit building in this area.

The Limit of Moderate Wave Action (LiMWA) was delineated in accordance with FEMA Procedure Memorandum 50 (2008). In coastal areas, Zone AE may be subdivided by a limit of moderate wave action boundary at the landward extent of the propagation of waves higher than 1.5 feet. Damages to structures from wave heights between 1.5 and 3 feet are similar to, but less severe than, those in areas where wave heights are greater than 3 feet, typically designated as Zone VE on the FIRM. Damages to structures from wave heights less than 1.5 feet are more similar to those in riverine or lacustrine floodplains. The inland limit of the area affected by waves greater than 1.5 feet is called the Limit of Moderate Wave Action (LiMWA).

3.4 Vertical Datum

Bench marks cataloged by the NGS and entered into the NSRS vary widely in vertical stability classification. NSRS vertical stability classifications are as follows:

- Stability A: Monuments of the most reliable nature, expected to hold position/elevation well (e.g., mounted in bedrock)
- Stability B: Monuments which generally hold their position/elevation well (e.g., concrete bridge abutment)
- Stability C: Monuments which may be affected by surface ground movements (e.g., concrete monument below frost line)

- Stability D: Mark of questionable or unknown vertical stability (e.g., concrete monument above frost line, or steel witness post)

In addition to NSRS bench marks, the FIRM may also show vertical control monuments established by a local jurisdiction; these monuments will be shown on the FIRM with the appropriate designations. Local monuments will only be placed on the FIRM if the community has requested that they be included, and if the monuments meet the aforementioned NSRS inclusion criteria.

All FISs and FIRMs are referenced to a specific vertical datum. The vertical datum provides a starting point against which flood, ground, and structure elevations can be referenced and compared. Previously, the standard vertical datum in use for newly created or revised FISs and FIRMs was the National Geodetic Vertical Datum (NGVD 29). With the finalization of the North American Vertical Datum of 1988 (NAVD 88), FIS reports and FIRMs are typically being prepared using NAVD 88 as the referenced vertical datum.

The conversion factor between NGVD 29 and NAVD 88 for Rockingham County is -.7 ft. Elevation 0 NGVD 29 is elevation -0.7 NAVD 88.

Flood elevations shown in this FIS report and on the FIRM for the following 14 coastal communities are referenced to NAVD 88: Greenland, Hampton, New Castle, Newfields, Newington, Newmarket, North Hampton, Portsmouth, Rye, Seabrook, Seabrook Beach Village District, and the Village District of Little Boar's Head. Structure and ground elevations in these communities must, therefore, be referenced to NAVD88.

Flood elevations shown in this FIS report and on the FIRMs for Exeter, Hampton Falls, and Stratham are referenced to NAVD88 on updated panels and streams, and remain in NGVD29 for panels that are not updated for the January 29, 2021 effective date (see the Index for effective dates per panel).

Flood elevations shown in this FIS report and on the FIRM for the 24 remaining, interior communities in Rockingham County, including Atkinson, Auburn, Brentwood, Candia, Chester, Danville, Deerfield, Derry, East Kingston, Epping, Fremont, Hampstead, Kensington, Kingston, Londonderry, Newton, Northwood, Nottingham, Plaistow, Raymond, Sandown, Salem, South Hampton, and Windham are referenced to NGVD29. Structure and ground elevations in these communities must, therefore, be referenced to NGVD 29. It is important to note that adjacent communities may be referenced to NAVD 88. This may result in differences in base flood elevations across the corporate limits between the communities.

A summary of the vertical datum reference by town in Rockingham County is provided in Table 9, "Vertical Datum Reference by Community."

TABLE 9 – VERTICAL DATUM REFERENCE BY COMMUNITY

Community Name	Vertical Datum Reference

For more information on NAVD 88, see Converting the National Flood Insurance Program to the North American Vertical Datum of 1988, FEMA Publication FIA-20/June 1992, or contact the Vertical Network Branch, National Geodetic Survey, Coast and Geodetic Survey, National Oceanic and Atmospheric Administration, Rockville, Maryland 20910 (Internet address <http://www.ngs.noaa.gov>).

4.0 FLOODPLAIN MANAGEMENT APPLICATIONS

The NFIP encourages State and local governments to adopt sound floodplain management programs. To assist in this endeavor, each FIS provides 1 percent annual chance floodplain data, which may include a combination of the following: 10-, 2-, 1-, and 0.2-percent annual chance flood elevations; delineations of the 1 percent annual chance and 0.2 percent annual chance floodplains; and 1 percent annual chance floodway. This information is presented on the FIRM and in many components of the FIS, including Flood Profiles, Floodway Data tables, and Summary of Stillwater Elevation tables. Users should reference the data presented in the FIS as well as additional information that may be available at the local community map repository before making flood elevation and/or floodplain boundary determinations.

4.1 Floodplain Boundaries

To provide a national standard without regional discrimination, the 1-percent annual chance (100-year) flood has been adopted by FEMA as the base flood for floodplain management purposes. The 0.2-percent annual chance (500-year) flood is employed to indicate additional areas of flood risk in the county. For the streams studied in detail, the 1 percent annual chance and 0.2 percent annual chance floodplain boundaries have been delineated using the flood elevations determined at each cross section.

Pre-countywide Analysis

Between the cross sections, the boundaries were interpolated using topographic maps (State of New Hampshire, 1970; USGS, 1956, 1966, 1973, 1974, 1977, 1981, 1985; James W. Sewall Company, 1976, 1977, 1978, 1979; Southeastern New Hampshire Regional Planning Commission, New Hampshire, August 1974; Avis Airmap, 1977; Southeastern New Hampshire Regional Planning Commission, Concord, New Hampshire, July 1975; and Underwood Engineers) and soil survey maps (U.S. Department of Agriculture, 1980, 1981, 1983, and 1986).

For the streams studied by approximate methods, the 1 percent annual chance floodplain boundaries were delineated using a combination of the following: previously printed Flood Hazard Boundary Maps (U.S. Department of Housing and Urban Development, 1974, 1975, 1976, 1977; FEMA, 1986); previously printed FISs (FEMA, 1981 and 1988); topographic maps (USGS, 1953, 1956, 1966, 1968, 1973, 1974, and 1981; James W. Sewall Company, 1976, 1977, 1979; S.N.H.R.P.C., 1975, 1976); SCS Flood Prone Area Map (U.S. Department of Agriculture, 1974); and soil survey map (U.S. Department of Agriculture, 1983).

The 1 percent annual chance and 0.2 percent annual chance floodplain boundaries are shown on the FIRM (Exhibit 2). On this map, the 1 percent annual chance floodplain boundary corresponds to the boundary of the areas of special flood hazards (Zones A and AE), and the 0.2 percent annual chance floodplain boundary corresponds to the boundary of areas of moderate flood hazards. In cases where the 1 percent annual chance and 0.2 percent annual chance floodplain boundaries are close together, only the 1 percent annual chance floodplain boundary has been shown. Small areas within the floodplain boundaries may lie above the flood elevations but cannot be shown due to limitations of the map scale and/or lack of detailed topographic data.

For the streams studied by approximate methods, only the 1 percent annual chance floodplain boundary is shown on the FIRM (Exhibit 2).

1 percent annual chance flood data elevations are shown in Table 10, "1% Annual Chance Flood Data."

(ALL JURISDICTIONS)**

1% ANNUAL CHANCE FLOOD DATA

HOG HILL BROOK

2005 Countywide Analyses

No remapping was conducted in 2005.

The January 29, 2021 Countywide Revision

For streams studied in detail, 1-percent and 0.2-percent annual chance floodplain boundaries were delineated using the flood elevations determined at each cross section. Between cross sections, the boundaries were interpolated based on 2-foot contour interval topography from the 2011 LiDAR mission discussed in Section 2.1. The LiDAR was also utilized to support the basic Zone A modeling and delineations, as well as the redelineation of hydraulic analyses from previous studies.

For tidal areas without wave action, the 1 percent annual chance and 0.2 percent annual chance flood boundaries were also delineated using the 2011 LiDAR. For the tidal areas with wave action, the flood boundaries were delineated using the elevations determined at each transect; between transects, the boundaries were interpolated using engineering judgment, land-cover data, and the topographic maps referenced above. The 1 percent annual chance floodplain was divided into whole-foot elevation zones based on average wave envelope elevation in that zone. Where the map scale did not permit these zones to be delineated at one-foot intervals, larger increments were used.

4.2 Floodways

Encroachment on floodplains, such as structures and fill, reduces flood-carrying capacity, increases flood heights and velocities, and increases flood hazards in areas beyond the encroachment itself. One aspect of floodplain management involves balancing the economic gain from floodplain development against the resulting increase in flood hazard. For purposes of the NFIP, a floodway is used as a tool to assist local communities in this aspect of floodplain management. Under this concept, the area of the 1 percent annual chance floodplain is divided into a floodway and a floodway fringe. The floodway is the channel of a stream, plus any adjacent floodplain areas, that must be kept free of encroachment so that the 1 percent annual chance flood can be carried without substantial increases in flood heights. Minimum federal standards limit such increases to 1.0 foot, provided that hazardous velocities are not produced. The floodways in this FIS are presented to local agencies as minimum standards that can be adopted directly or that can be used as a basis for additional floodway studies.

The floodways presented in this FIS were computed for certain stream segments on the basis of equal conveyance reduction from each side of the floodplain. Floodway widths were computed at cross sections. Between cross sections, the floodway boundaries were interpolated. The results of the floodway computations are tabulated for selected cross sections (Table 11). The computed floodways are shown on the FIRM (Exhibit 2). In cases where the floodway and 1 percent annual chance floodplain boundaries are either close together or collinear, only the floodway boundary is shown.

TABLE 11

FEDERAL EMERGENCY MANAGEMENT AGENCY

ROCKINGHAM COUNTY, NH

(ALL JURISDICTIONS)

FLOODWAY DATA

WINNICUT RIVER

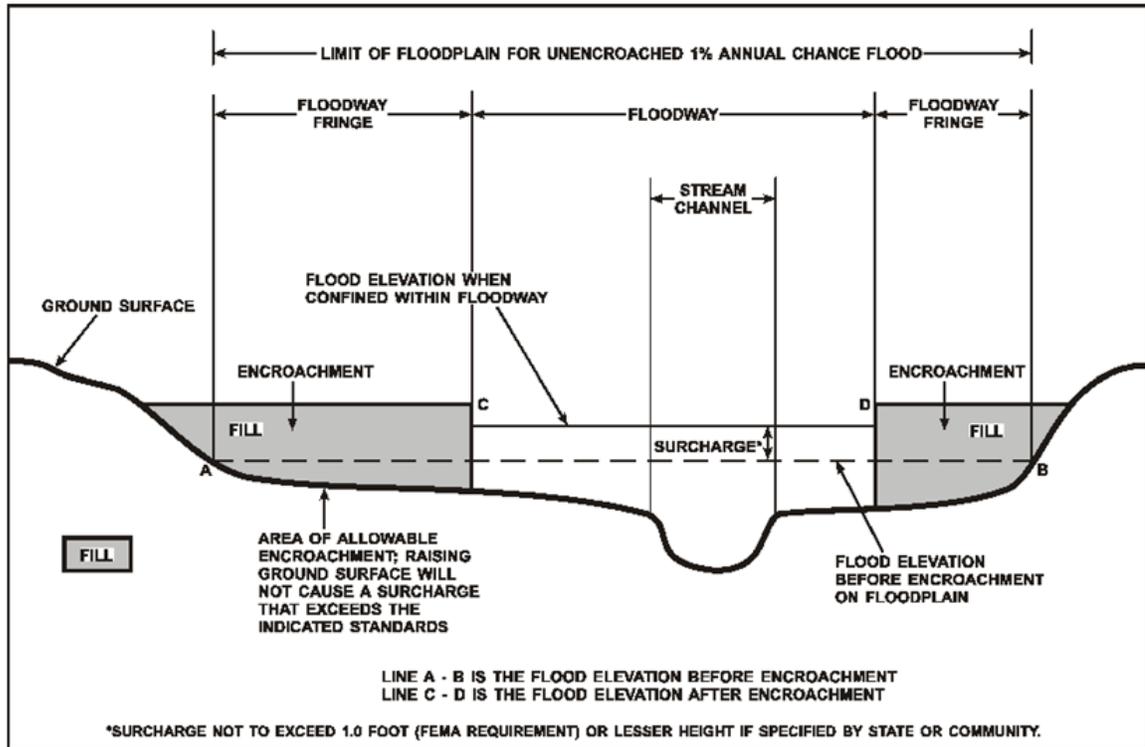

Portions of the floodways for Beaver Brook extend beyond the county boundary. No floodway was computed for Grassy Brook, Hill Brook, Hog Hill Brook, Porcupine Brook, Porcupine Brook Tributary, Powwow River (Downstream Reach), Powwow River (Upstream Reach), Squamscott River, Wash Pond Tributary, West Channel Policy Brook, and portions of the Lamprey River and Pickering Brook.

Encroachment into areas subject to inundation by floodwaters having hazardous velocities aggravates the risk of flood damage, and heightens potential flood hazards by further increasing velocities. A listing of stream velocities at selected cross sections is provided in Table 11, "Floodway Data." In order to reduce the risk of property damage in areas where the stream velocities are high, the community may wish to restrict development in areas outside the floodway.

Near the mouths of streams studied in detail, floodway computations are made without regard to flood elevations on the receiving water body. Therefore, "Without Floodway" elevations presented in Table 10 for certain downstream cross sections of Black Brook, Hidden Valley Brook, Homes Brook, Little River No. 1, Tributary C to Beaver Brook, Tributary G to Beaver Brook, Tributary O to Beaver Brook, Tributary E to Little Cohas Brook, and Tributary H to Nesenkeag Brook are lower than the regulatory flood elevations in that area, which must take into account the 1 percent annual chance flooding due to backwater from other sources.

The area between the floodway and 1 percent annual chance floodplain boundaries is termed the floodway fringe. The floodway fringe encompasses the portion of the floodplain that could be completely obstructed without increasing the water-surface elevation of the 1 percent annual chance flood by more than 1.0 foot at any point. Typical relationships between the floodway and the floodway fringe and their significance to floodplain development are shown in Figure 3.

Figure 3: Floodway Schematic

5.0 INSURANCE APPLICATIONS

For flood insurance rating purposes, flood insurance zone designations are assigned to a community based on the results of the engineering analyses. The zones are as follows:

Zone A

Zone A is the flood insurance rate zone that corresponds to the 1 percent annual chance floodplains that are determined in the FIS by approximate methods. Because detailed hydraulic analyses are not performed for such areas, no base flood elevations or depths are shown within this zone.

Zone AE

Zone AE is the flood insurance rate zone that corresponds to the 1 percent annual chance floodplains that are determined in the FIS by detailed methods. In most instances, whole-foot base flood elevations derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

Zone AO

Zone AO is the flood insurance rate zone that corresponds to the areas of 1 percent annual chance shallow flooding (usually sheet flow on sloping terrain) where average depths are between 1 and 3 feet. Average whole-foot depths derived from the detailed

hydraulic analyses are shown within this zone.

Zone V

Zone V is the flood insurance rate zone that corresponds to the 1 percent annual chance coastal floodplains that have additional hazards associated with storm waves. Because approximate hydraulic analyses are performed for such areas, no base flood elevations are shown within this zone.

Zone VE

Zone VE is the flood insurance rate zone that corresponds to the 1 percent annual chance coastal floodplains that have additional hazards associated with storm waves. Whole-foot base flood elevations derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

Zone X

Zone X is the flood insurance rate zone that corresponds to areas outside of the 0.2 percent annual chance floodplain, areas within the 0.2 percent annual chance floodplain, and to areas of 1 percent annual chance flooding where average depths are less than 1 foot, areas of 1 percent annual chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 1 percent annual chance flood by levees. No base flood elevations or depths are shown within this zone.

6.0 FLOOD INSURANCE RATE MAP

The FIRM is designed for flood insurance and floodplain management applications.

For flood insurance applications, the map designates flood insurance rate zones as described in Section 5.0 and, in the 1 percent annual chance floodplains that were studied by detailed methods, shows selected whole-foot base flood elevations or average depths. Insurance agents use the zones and base flood elevations in conjunction with information on structures and their contents to assign premium rates for flood insurance policies.

For floodplain management applications, the map shows by tints, screens, and symbols, the 1 percent annual chance and 0.2 percent annual chance floodplains. Floodways and the locations of selected cross sections used in the hydraulic analyses and floodway computations are shown where applicable.

The current FIRM presents flooding information for the entire geographic area of Rockingham County. Prior to the 2005 countywide study, separate FIRMs were prepared for each identified flood-prone incorporated community in the county. The countywide FIRM also included flood hazard information that was presented separately on FBFMs, where applicable. Historical data relating to the maps prepared for each community are presented in Table 12, "Community Map History."

¹ The land area for this community was previously shown on the FHBM for the Town of Seabrook as a portion of the town. It has now been identified as a separate NFIP community. Therefore, the dates for this community were taken from the FHBM for the Town of Seabrook.

² The land area for this community was previously shown on the FIRM for the Town of North Hampton as a portion of the town. It has now been identified as a separate NFIP community. Therefore, the dates for this community were taken from the FIRM for the Town of North Hampton.

³ This community did not have a published map prior to the first time countywide for Rockingham County, New Hampshire.

7.0 OTHER STUDIES

Information pertaining to revised and unrevised flood hazards for each jurisdiction within Rockingham County has been compiled into this FIS. Therefore, this FIS supersedes all previously printed FIS reports, FBFMs, and FIRMs for all jurisdictions within Rockingham County.

This is a multi-volume FIS. Each volume may be revised separately, in which case it supersedes the previously printed volume. Users should refer to the Table of Contents in Volume 1 for the current effective date of each volume; volumes bearing these dates contain the most up-to-date flood hazard data.

8.0 LOCATION OF DATA

Information concerning the pertinent data used in the preparation of this FIS Report can be obtained by submitting an order with any required payment to the FEMA Engineering Library. For more information on this process, see <http://www.fema.gov>.

Figure 4: FIRM Notes to Users

NOTES TO USERS

For information and questions about this map, available products associated with this FIRM including historic versions of this FIRM, how to order products, or the National Flood Insurance Program in general, please call the FEMA Mapping and Insurance eXchange at 1-877-FEMA-MAP (1-877-336-2627) or visit the FEMA Map Service Center website at <http://msc.fema.gov>. Available products may include previously issued Letters of Map Change, a Flood Insurance Study Report, and/or digital versions of this map. Many of these products can be ordered or obtained directly from the website. Users may determine the current map date for each FIRM panel by visiting the FEMA Map Service Center website or by calling the FEMA Mapping and Insurance eXchange.

Communities annexing land on adjacent FIRM panels must obtain a current copy of the adjacent panel as well as the current FIRM Index. These may be ordered directly from the Map Service Center at the number listed above.

For community and countywide map dates, refer to Section 6 this FIS Report.

To determine if flood insurance is available in the community, contact your insurance agent or call the National Flood Insurance Program at 1-800-638-6620.

The map is for use in administering the NFIP. It may not identify all areas subject to flooding, particularly from local drainage sources of small size. Consult the community map repository to find updated or additional flood hazard information.

BASE FLOOD ELEVATIONS: For more detailed information in areas where Base Flood Elevations (BFEs) and/or floodways have been determined, consult the Flood Profiles and Floodway Data and/or Summary of Stillwater Elevations tables within this FIS Report. Use the flood elevation data within the FIS Report in conjunction with the FIRM for construction and/or floodplain management.

Coastal Base Flood Elevations shown on the map apply only landward of 0.0' North American Vertical Datum of 1988 (NAVD88). Coastal flood elevations are also provided in the Coastal Transect Parameters table in the FIS Report for this jurisdiction. Elevations shown in the Coastal Transect Parameters table should be used for construction and/or floodplain management purposes when they are higher than the elevations shown on the FIRM.

FLOODWAY INFORMATION: Boundaries of the floodways were computed at cross sections and interpolated between cross sections. The floodways were based on hydraulic considerations with regard to requirements of the National Flood Insurance Program. Floodway widths and other pertinent floodway data are provided in the FIS Report for this jurisdiction.

NOTES FOR FIRM INDEX

REVISIONS TO INDEX: As new studies are performed and FIRM panels are updated within Rockingham County, New Hampshire (All Jurisdictions), corresponding revisions to the FIRM Index will be incorporated within the FIS Report to reflect the effective dates of those panels. Please refer to Table 12 of this FIS Report to determine the most recent FIRM revision date for each community. The most recent FIRM panel effective date will correspond to the most recent index date.

SPECIAL NOTES FOR SPECIFIC FIRM PANELS

This Notes to Users section was created specifically for Rockingham County, New Hampshire (All Jurisdictions), effective January 29, 2021.

LIMIT OF MODERATE WAVE ACTION: The Zone AE category has been divided by a Limit of Moderate Wave Action (LiMWA). The LiMWA represents the approximate landward limit of the 1.5-foot breaking wave. The effects of wave hazards between the VE Zone and the LiMWA (or between the shoreline and the LiMWA for areas where VE Zones are not identified) will be similar to, but less severe than those in the VE Zone.

Flood elevations on this map are referenced to either the National Geodetic Vertical Datum of 1929 (**NGVD29**) or the North American Vertical Datum of 1988 (NAVD88). Additional information is available in Section 3 of the accompanying Flood Insurance Study report. Note that flood elevations must be compared to structure and ground elevations referenced to the same vertical datum. For information regarding conversion between the National Geodetic Vertical Datum of 1929 (**NGVD29**) and the North American Vertical Datum of 1988 (NAVD88), visit the National Geodetic Survey website at <http://www.ngs.noaa.gov> or contact the National Geodetic Survey at the following address:

FLOOD RISK REPORT: A Flood Risk Report (FRR) may be available for many of the flooding sources and communities referenced in this FIS Report. The FRR is provided to increase public awareness of flood risk by helping communities identify the areas within their jurisdictions that have the greatest risks. Although non-regulatory, the information provided within the FRR can assist communities in assessing and evaluating mitigation opportunities to reduce these risks. It can also be used by communities developing or updating flood risk mitigation plans. These plans allow communities to identify and evaluate opportunities to reduce potential loss of life and property. However, the FRR is not intended to be the final authoritative source of all flood risk data for a project area; rather, it should be used with other data sources to paint a comprehensive picture of flood risk.

Each FIRM panel contains an abbreviated legend for the features shown on the maps. However, the FIRM panel does not contain enough space to show the legend for all map features. Figure 5 shows the full legend of all map features. Note that not all of these features may appear on the FIRM panels in Rockingham County.

Figure 5: Map Legend for FIRM

SPECIAL FLOOD HAZARD AREAS: *The 1% annual chance flood, also known as the base flood or 100-year flood, has a 1% chance of happening or being exceeded each year. Special Flood Hazard Areas are subject to flooding by the 1% annual chance flood. The Base Flood Elevation is the water surface elevation of the 1% annual chance flood. The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights. See note for specific types. If the floodway is too narrow to be shown, a note is shown.*

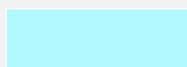

Special Flood Hazard Areas subject to inundation by the 1% annual chance flood (Zones A, AE, AH, AO, AR, A99, V and VE).

- Zone A The flood insurance rate zone that corresponds to the 1% annual chance floodplains. No base (1% annual chance) flood elevations (BFEs) or depths are shown within this zone.
- Zone AE The flood insurance rate zone that corresponds to the 1% annual chance floodplains. Base flood elevations derived from the hydraulic analyses are shown within this zone, either at cross section locations or as static whole-foot elevations that apply throughout the zone.
- Zone AH The flood insurance rate zone that corresponds to the areas of 1% annual chance shallow flooding (usually areas of ponding) where average depths are between 1 and 3 feet. Whole-foot BFEs derived from the hydraulic analyses are shown at selected intervals within this zone.
- Zone AO The flood insurance rate zone that corresponds to the areas of 1% annual chance shallow flooding (usually sheet flow on sloping terrain) where average depths are between 1 and 3 feet. Average whole-foot depths derived from the hydraulic analyses are shown within this zone.
- Zone AR The flood insurance rate zone that corresponds to areas that were formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.
- Zone A99 The flood insurance rate zone that corresponds to areas of the 1% annual chance floodplain that will be protected by a Federal flood protection system where construction has reached specified statutory milestones. No base flood elevations or flood depths are shown within this zone.
- Zone V The flood insurance rate zone that corresponds to the 1% annual chance coastal floodplains that have additional hazards associated with storm waves. Base flood elevations are not shown within this zone.
- Zone VE Zone VE is the flood insurance rate zone that corresponds to the 1% annual chance coastal floodplains that have additional hazards associated with storm waves. Base flood elevations derived from the coastal analyses are shown within this zone as static whole-foot elevations that apply throughout the zone.

Regulatory Floodway determined in Zone AE.

Non-encroachment zone (see Section 2.4 of this FIS Report for more information)

OTHER AREAS OF FLOOD HAZARD

Shaded Zone X: Areas of 0.2% annual chance flood hazards and areas of 1% annual chance flood hazards with average depths of less than 1 foot or with drainage areas less than 1 square mile.

Future Conditions 1% Annual Chance Flood Hazard – Zone X: The flood insurance rate zone that corresponds to the 1% annual chance floodplains that are determined based on future-conditions hydrology. No base flood elevations or flood depths are shown within this zone.

Area with Reduced Flood Risk due to Levee: Areas where an accredited levee, dike, or other flood control structure has reduced the flood risk from the 1% annual chance flood.

OTHER AREAS

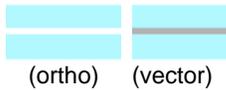

Zone D (Areas of Undetermined Flood Hazard): The flood insurance rate zone that corresponds to unstudied areas where flood hazards are undetermined, but possible.

Unshaded Zone X: Areas of minimal flood hazard.

FLOOD HAZARD AND OTHER BOUNDARY LINES

Jurisdictions Included in the Flood Insurance Study Project

This FIS Report covers the entire geographic area of Rockingham County, New Hampshire.

The jurisdictions that are included in this project area, along with the Community Identification Number (CID) for each community and the 8-digit Hydrologic Unit Codes (HUC-8) sub-basins affecting each, are shown in Table 14. The Flood Insurance Rate Map (FIRM) panel numbers that affect each community are listed. If the flood hazard data for the community is not included in this FIS Report, the location of that data is identified.

The location of flood hazard data for participating communities in multiple jurisdictions is also indicated in the table.

Jurisdictions that have no identified SFHAs as of the effective date of this study are indicated in the table. Changed conditions in these communities (such as urbanization or annexation) or the availability of new scientific or technical data about flood hazards could make it necessary to determine SFHAs in these jurisdictions in the future.

TABLE 14 – LISTING OF NFIP JURISDICTIONS

Community	CID	HUC-8 Sub-Basin(s)	Located on FIRM Panel(s)	If Not Included, Location of Flood Hazard Data
